Intend in this Effay to give fome account of the Nature of Evaporation, the Ascent of Watery Vapours and seve-

ral other Phanomena of the Atmosphere. In explaining which I shall proceed upon

* This Essay was read at a Meeting of the Royal Society on the 9th and 16th of May, 1765, communicated in a Letter to the Rev. Charles Dodg son, D. D. F. R. S. now Lord Bishop of Osfory. Vide Phil. Trans. Vol. LIV. To which some Additions and Improvements have been since made by the Author.

a Principle very different (as far as I can find) from any that has hitherto been used on this Occasion; whereby I shall avoid those Objections which late Writers have made to the former Accounts that have been given us of these Phænomena, and perhaps deliver something on this Subject that may appear satisfactory.

In all the Accounts I have met with, Fire, or Heat and Rarefaction, by which Watery Vapours are supposed to become fpecifically lighter than Air, are made to be the principal, if not the only Causes of their Ascent into the Atmosphere. Doctor Niewentyt, and some others supposed, that the Particles of Fire, by adhering to those of Water, make up Moleculæ or fmall Bodies specifically lighter than Air. And Doctor Halley thought. that by the Action of Heat the Particles of Water are formed into hollow Spherules filled with a finer Air, highly rarefied, so as to become specifically lighter than the external Air. This last was the Opinion most commonly received, as Doctor Desaguliers tells us in his Differtation

tation on this Subject (published in The Philosophical Transactions, in the Year 1729) in which he examines and refutes the two former Opinions, and endeavours to establish his own. He ascribes the Ascent of Aqueous Vapours to their being turned into an Elastic Steam, and always rarefied more than the Air is by the Degrees of Heat, to which Bodies are usually subject in the different Seasons of the Year.

This Opinion, I find, has been as ill received by subsequent Writers, as the former ones, Mr. Clare, in his Treatise on the Motion of Fluids, has brought many Objections against it; as Mr. Rowning has also done in his System of Natural Philosophy, not long since published; who says, that the Cause of the Ascent of Vapours has been much disputed, but not yet determined by Philosophers, and owns that he cannot think of any true Principle of Philosophy upon which it may be accounted for.

fish of world have Biolinian fave her thall

I shall not here repeat the Objections made by those Gentlemen, but must beg leave to add the two following, which, among others that might still be urged, they have not taken Notice of.

First; If Heat was the only Cause of Evaporation, Water in a warm and close Room would evaporate faster than when exposed in a colder Place where there is a constant Current of Air, which is contrary to Experience.

Secondly; The Evaporation of Water is so far from depending on its being rare-fied by Heat, that it is carried on even whilst Water is condensed by the Coldness of the Air. For Water is gradually condensed by Cold, 'till the Moment it freezes; and since it evaporates even when frozen into hard ice, it must evaporate in all the lesser Degrees of Cold. Mr. Boyle, having counterpoised a Piece of Ice in a Scale, hung it out in a frosty Night, and found next Morning that it lost considerably of its Weight by Evaporation, "Who would have thought, says he, that

"fo extremely hard and cold a Body "would evaporate fo fast in the clear Air of a freezing Night?" and since that time others have observed the same Thing; which Fast seems to be an unanswerable Objection to all the Accounts in which Rarefaction by Heat is made to be the chief, if not the only Cause of Evaporation: and therefore we must have Recourse to some other Principle to affist us in accounting for this Phænomenon.

As the Author of Nature does not employ in his Works a greater Variety of Causes than is absolutely necessary, it is the Bufiness of natural Philosophy to reduce as many Phænomena as may be, to fome general well-known Caufe; and this is to be done by comparing the Phænomena together in their feveral Circumilances, in which if they are found to agree, they are then to be confidered as Effects of the fame Kind, and afcribed to the fame Cause; by which Means, the Causes, whose Existence is already proved, will be rendered more general, and our Knowledge more extensive. Now, as the B 3 Sufpension

Sufpension of the Particles of Water in Air, of Salt in the Waters of the Ocean, and of other heavy Bodies in the Fluids that diffolve them, feem to be Phænomena of the fame Kind, we might reasonably suppose, that they arise from the fame Caufe, and that what we call Evaporation is nothing more than a gradual Solution of water in Air. But that I may not propose this merely as an Hypothesis, I shall endeavour to prove the Truth of it, by confidering the Nature of Solution in general, and comparing its Properties and Effects with those of Evapora-Caules than is abfolutely necessary, noit. the Businels of catural Phile color to be

By Solution we understand, such an intimate Union between the Particles of a Body and those of a Fluid, that the Whole shall appear an Homogeneous Mass, as transparent as the Fluid was before such Union, and shall so continue, till some external Gause produces a Change. The Nature of Solution has been explained by the Writers on Chymistry in this Manner; When the Particles of any Body surrounded by a Fluid are less

less dirongly attracted by each other than by the Fluid, they must feparate from each other, and join themselves to those of the Fluid, and remain suspended therein: Thus various Salts are diffolved in Water, effential Oils in Spirits of Wine, Gold in Aqua Regia, Mercury, Silver and other Metals in other acid Spirits; and indeed it feems to be with great Appearance of Reafon, that the Attraction between the minute Particles of different Bodies (of which we have fo many other Inflances) is affigned as the Caufe of that Umon between them, which we experience in Solutions; the chief Properties of which I shall now mention, so far as may be necesfary for the Purpole to which I mean to apply them.

In most Cases a dissolving Fluid, or Menstruum as the Chymists call it, will dissolve or take up only a certain Quantity of the Body which is soluble in it, and if any more of the same Body be added, it will fall undissolved to the Bottom, and then the Fluid is said to be saturated with the Body it has dissolved; yet a Fluid which

is faturated with one Body may afterwards dissolve others of different Kinds, and keep all their Particles suspended together.

When any Menstruum has entirely diffolved a Body, it will continue as transparent as it was before; the Cause of which may be affigned from what Sir Isaac Newton discovered by Experiments, viz. that the Particles of Bodies must be of a certain Size or Bigness to cause those Reflections or Refractions of the Rays of Light at their Surfaces to which Opacity is owing; whence he gives the Reason, why fome Bodies are opake and others transparent. He also observes, that the most opake Bodies (such as Metals) being dissolved in an acid Menstruum, and thereby reduced to their ultimate and fmalleft Particles, do not take away the Transparency of the Menstruum.

Hence we may always know how to diftinguish a Solution from a Mixture. For, if a Body be reduced to Powder and thrown into a Fluid that will dissolve it,

ties

and they are then shaken suddenly together, the Fluid will continue domewhat opake, till the Solution be effected, or till what remains undiffolved falls to the Bottom; for in this Cafe, the Particles are not at first reduced to their smallest Size as they always are in a Solution. And therefore the Chymists consider the Transparency of an heterogeneous Fluid for one that contains in it Particles of another Body) as the Criterion of a true Solution; and where that is wanting, it is only -a Mixtures as when Water and Air appear together in Froth, or in a Cloud, or a thick Mift, it is only a Mixture of those Bodies; and not a Solution of one in the on between the Particles of Arith

This much being premited concerning the Nature of Solutions in general, I proliced to the Proof of what I proposed; and in Ordento this, I shall shew that there is a mutual Attraction between Water and Air, the same that we observe between the Particles of any two Bodies, one of which distolves the other. I shall then compare, in several instances, the Proper-

-000

ties and Effects of common Solutions with with those of Evaporation; that from the exact Resemblance between these two Phænomena, it may appear that they are Effects of a like Kind, and therefore to be explained upon the same Principle, or ascribed to the same Cause. Thence I shall shew, how the Ascent of Vapours, and several other Phænomena of the Atmosphere may be accounted for. And lastly, I shall add something on the rising of Steam from boiling Liquors, and shew wherein it differs from common Evaporation.

I am first to prove that there is an Attraction between the Particles of Air and Water. It is well known, that all Water contains a considerable Quantity of Air, that this Air retains its Elasticity so that it may be separated from the Water by boiling and including it in an exhausted Receiver. It has also been proved by Experiments, that Air extricated from Water by boiling, and restored to its usual Density, will ocupy a Space greater than that possessed by the Water in which it was

contained. New fince it is allowed that the Particles of fo heavy a Body as Gold are suspended in Aque Regia by their Attraction towards the Particles of that Fluid, it seems reasonable to suppose, that so light and elastic a Body as Air must be retained under Water by a like Force, without which it would always ascend to the Surface and escape. But that there is really such an attractive Force between Air and Water, may be fully proved by the following Experiment.

Let an Oil-Flack be filled almost full with Water, deprived of its Air as much as may be; let the mouth of it be then stopped, until the Neck, being inverted, is immersed in a Vessel of Water; a Bubble of Air will then ascend into the upper Part of the Flask. When Things have stood in this Way for some Days, the Water will be found to have absorbed the whole Bubble of Air (if it was not too large) and entirely filled the Flask. But if the Bubble was too large, Part of it will be left; for the Water, after some Time, will absorb no more Air, being then

then sufficiently saturated with it. It is observable that the included Air enters pretty quickly into the Water at sirst, but afterwards very slowly. This Experiment shews that Water, when deprived of its Air, will again draw the Air gradually into its Pores; just in the same Manner as a Lump of dry Sugar will draw up Water into its Pores, which will ascend pretty quickly at first, but very slowly after some Time. We have Reason therefore to conclude, that there is the same kind of Attraction between Air and Water, that there is between Water and any stry porous Body that will imbibe it.

As Water contains a confiderable Quantity of Air, so does Air contain a good deal of Water, even when we think it quite pure and dry; as appears from the Moisture drawn from it by dry Salt of Tartar, in such Quantity as to make the Salt become entirely fluid. Now since the Air is an heterogeneous Fluid containing in it Particles of another Body, and yet retaining a perfect Transparency, which is the Criterion of a true Solution

in other Cases; why should we not infer from Analogy, that in this Case also there is a true Solution of Water in Air?

But the Truth of this will be confirmed by farther comparing the Properties of common Solutions with those of Evaporation; which I shall now do in several Instances.

First; When a Body is immerfed in a Fluid that dissolves it, for Instance a Lump of Salt in Water, we see the Salt soon begin to dissolve, and impregnate with its Particles the Water that furrounds it, which will then appear thick and loaded, and if the Water be at Rest the Solution will proceed very flowly; but if it be flirred about, the Salt will foon be entirely diffolved. How exactly does this correspond with what Dr. Halley remarked in an Experiment he made on the Evaporation of Water in a close Room? (Philof. Trans. No. 192.) " The fame Observations, fays he, " do likewife flew an odd Quality in the " Vapours of Water, which is, that of " adhering to the Surface that exhales " them, which they clothe as it were

e

7,

n

" with a Fleece of vapourous Air, which " once investing it, the Vapour rifes af-" terwards in much less Quantity." Here we fee, that the Air which lay at rest over the Water appeared thick and loaded with the aqueous Particles, and then the Evaporation proceeded very flowly; just as the Water that lies about the Salt, appears thick and loaded, and while it continues at rest, the Salt is dissolved but slowly. He also observes on the same Occasion, that Evaporation is vallly promoted by a Current of fresh Air passing over the exhaling Surface: and this I have no doubt happens for the fame Reason that Solution is greatly promoted by Agitation, which continually brings fresh Particles of the Fluid into Contact with the Body it dissolves, in the Place of those that have been already faturated. [A]

Secondly;

[A] This Pleece of vapourous Air that sometimes hangs over Water, is very discernable when we stand by the Sea-side in a hot calm Day, and is the Cause of some odd Appearances. For the lower part of the Air, which is then

Secondly; Into a Glass of clear cold Water throw a Lump of Salt, and when it has flood a little Time, flir it very gently, and the Water which is faturated with the Salt will rife up among the rest in curled Wreaths or long Striæ, which will render the Whole somewhat opake, eausing it to refract the Rays of Light in different Directions, which will make an Object feen through it appear to have a tremulous Motion: this will continue until all Parts of the Water are equally impregnated with the Salt, and then its Transparency will be restored. As the Parts of the Water which are impregnated with the Salt are of diffesent Denfities from the reft, while they are mixing together, they must occasion those Refractions and this apparent tremu-

then much impregnated with Water, refracts the Rays of the Light more strongly than at other Times, and by this unusual Degree of Refraction, Houses on the Shore at a Distance from us appear almost as high as Steeples, remote Ships and Islands and the extreme Parts of Head-lands or Promontories appear to be raised quite out of the Water, and to hang in the Air above its Surface.

lous Motion, which will cease as soon as all the Water becomes of the same Density. The very same Appearances will attend the mixing together of any two Fluids which have different Densities, and will thoroughly incorporate with each other.

In like manner, when Smoke or Steam, iffuing from the Pipe of a boiling Veffet, first rifes into the Air, it appears in curled Wreaths, and renders the Air opake; but as foon as it is entirely dispersed, the Transparency is reflored. Thus also in a calm, hot, Sun-shine Day, when we look along a moist piece of Ground, the Air and any Objects feen through it appear to have a tremulous Motion, like that which we obferve in an Object, feen through two Fluids which are mixing together. Now, as the Vapours rife here in great Abundance and the Air has but little Motion, those Parts of it that are much impregnated with aqueous Particles are mixed gradually with the Air above it that is drier and of a different Denfity; which will occasion Refractions of the Light, and that that apparent tremulous Motion, just now mentioned; and in this Gafe, the Solution of Water in Air (if I may yet venture to call it by that Name) is carried on in a Manner visible to the Eye, as Solutions are in other Fluids. The fame tremulous undulating Motion is more observable, when we look in warm Weather through a Telescope, which magnifies the Vapours floating in the Air: and from this kind of Refraction the twinkling of the Stars feems to arise; with this Difference only, that the watery refracting Particles in the Daytime are passing into a State of Solution; whereas the Vapours already diffolved are by the Cold of the Night beginning to precipitate, and return into Particles large enough to cause Refractions in the Light. of the Stars

Thirdly; Heat promotes, and Cold in fome Measure stops or checks both Solution and Evaporation. Very hot Water will dissolve Salt sooner and in a greater Quantity than cold Water; and if a strong Solution of Salt be made in hot Water, the Water when cold will let go some of

C 3

the Salt before diffolved, which will fall to the Bottom in small Particles or shoot into Chrystals. Just so will Water evaporate faster in warm than in cold Air; and the aqueous Vapours, suspended in the Air during the Heat of the Day, fall down at Night and form themselves into Drops of Daw, or if the Night be very cold appear next Morning Chrystalized, in a HOAR-FROST. And thus if in a hot Day a Bottle be filled with any very cold Liquor, and exposed to the warm Air, which to us feems very dry, a Dew will be foon formed on the outlide of the Bottle: for the Air about it being cooled will let go Part of its Moillure, which will be attracted to the Surface of the Glas; for the fame Reason a Dew is formed on the Infide of the Windows of a warm Room, which on their Outfide are exposed to the cold Air. In like Manner, the Moisture breathed out from the Lungs of Animals becomes visible in very cold Air, which cannot keep that Moisture in a State of Solution, as warm Air will do. Hence also we may observe, that as there cannot be fo continual and copious an Eyaporation

Evaporation in cold weather, the Air will then be generally clearer than it is in hot Weather.

Heat feems to promote Solution, because it expands Bodies, and thereby enlarges their Pores, and lessens the cohesive Attraction of their Particles; so that a Body, when hot, will more easily admit a dissolving Fluid into its Pores, and its Particles, cohering together less strongly than when cold, will more readily quit each other, and unite themselves to the Particles of the Fluid by which they are attracted; and for the same Reason Heat will also promote the Evaporation of Fluids.

But fourthly; The Quantity of a Body dissolved, and of a Fluid evaporated, in a given Time, depends (cateris paribus) on its Quantity of Surface. Thus a Body reduced to Powder is sooner dissolved than it is in a concrete Form; and thus Smoak or Steam (which is Water reduced to very small Particles by Heat) is much sooner dispersed and incorporated with Air, than Water

Water in its usual Form. Thus likewise the Moissure, which adheres to a cold polished Plate of Glass or Metal, when we breathe upon it, is immediately dried up by the Air, because it is exceedingly thin and has a very great Surface.

Fifthly; Chymists observe, that when Sea-Salt, Sal Ammoniac, or Nitre, is diffolved in Water, or effential Oils in Spirit of Wine, some Degree of Cold is produced in the immediate Act of Solution; and the quicker the Solution, the greater is the Cold. By diffolving pounded Ice, or rather Snow (whose Particles have a greater Surface) in Spirit of Nitre, a Degree of Cold has been produced fo great as to freeze Quick-filver. Cold is likewise produced in the Act of Evaporation. For if Spirit of Wine, or Æther, be rubbed lightly with a Feather over the Ball of a Thermometer, it will fink as the Spirit evaporates; and the quicker the Evaporation, the faster will the Thermometer fink; thus I have made Water freeze in a thin Glass merely by the Evaporation of Æther promoted promoted by a Current of Air. That Cold is produced by the Evaporation of Water appears from the Practice of Sailors, who, in hot Climates, cool their Liquors by wrapping the Veffels in wet Cloths, and hanging them up where they are much exposed to the Wind, and wetting the Cloths again when they become dry.

This Observation shews a very remarkable Agreement between the Natures of Solution and Evaporation: How the Cold is produced in either Case, I cannot pretend to fay; but I must beg leave just to apply this Fact, to account for a Thing which I believe most People have taken Notice of. If we rub Hungary Water, or any other volatile Spirit over our Hand, it will feel much colder than Water, tho' they will both feel equally cold, if we dip our Finger into each. The Reason of which is, that the Spirit evaporating much quicker than the Water, produces thereby a greater Degree of Cold. And fo Æther, if it be applied in the fame Way, will feel

of its more sudden Evaporation.

Spirit of Wine, when purged of Air, will imbibe a large Bubble of Air in a much shorter Time than Water will do, and I have myself experienced the Truth of this, which shews that there is a stronger Attraction, or Affinity. (as the Chymists call it) between Spirit of Wine and Air, than between Water and Air, and since the Spirit evaporates much faster than the Water, I think we may conclude from hence, that the Evaporation of Fluids arises from an attractive Force between their Particles and those of Air. [8] But here it must be observed

[s] As Water and Spirit of Wine are in no Degree viscid, they may evaporate in Proportion to the Attraction between them and Air. But the Case is very different in such Fluids as are viscid; for tho' I found that Oil of Olives, when purged of Air, will imbibe a Bubble of Air almost as soon as Water does, yet the Evaporation of Oil, is scarcely (if at all) sensible. The Reason of which must be, that the Attraction

observed that the Spirit is not only more strongly attracted by the Air than Water is, but, being also more easily rarefied by Heat, its Particles seem to cohere together more slightly than those of Water, and therefore may be more easily separated by the Attraction of the Air.

Seventhly;

tion between Air and the Oil is not able to overcome the Tenacity of its Particles and separate them from each other, tho' it is sufficient to draw into the Oil the Particles of Air, which have no Attraction towards each other; just as Water is drawn into a Sponge, tho' the Attraction of the Water is not able to separate the Particles of the Sponge from each other. It might perhaps be supposed that the Water contained in the Air may defend the Oil from the Attraction of the Air, and thereby prevent the Oil from evaporating; but if this were the Case, the same Water would also defend the Air from the Attraction of the Oil, which we fee it does not. The Particles of Oil, like those of all other Fluids, may indeed be separated from each other and driven into the Air by a violent Heat; but this Effect must be distinguished from common Evaporation, as will appear from what is faid in the latter part of this Effay.

Seventhly; If into any Menstruum we throw a Body, which it diffolves, and afterwards add another, to which the Menstruum has a greater Affinity than it has to the first, it will dissolve the second Body, and let go the first, which will be precipitated and fall to the Bottom. In the very fame Manner will a Fluid let go the Air it contains, upon the Addition of another Body to which it has a greater Affinity than it has to the Air. Thus if to well rectified Spirit of Wine we add an equal Quantity of clear Rain-water, these Fluids (which fo readily incorporate) having a greater Affanity to each other than to the Air they contain, will let go a great Part of that Air, which will rife to the Top, or adhere in small Bubbles to the Sides of the Veffel. This, I think, thews that Air is contained in these Fluids, in the fame Manner that the Particles of a Body are contained in a Menstruse that diffolves it; and hence I conclude that the Air which is imbibed by any Fluid is, properly speaking, diffolued in that Fluid; and confequently that any Fluid which evaporates,

evaporates, or is imbibed by the Air, is alfo, properly speaking, dissolved in Air. Upon this Principle we may say, that Water is drawn out of Air by dry Salt of Tartar, from its having a greater Affinity to that Salt than to the Air.

I should not have been so tedious in comparing together the Natures of Solution and Evaporation in fo many Instances. but that it gave me an Opportunity at the fame Time of explaining fome of the Phænomena that I at first intended to confider; which Explanations I believe will be admitted, if I am right in the main Point I have endeavoured to prove. And really when we confider how exactly Solution and Evaporation agree, in their feveral Appearances, Properties and Effects, I think we must be convinced that they are natural Operations of the fame Kind, and that what we call Evaporation, is nothing more than a gradual Solution of Water in Air, produced and promoted by the same Means (to wit) Attraction, Heat, and Motion

Motion, by which other Solutions are effected.

I shall now endeavour to account for several Phænomena of the Atmosphere upon this Principle, which will be still further confirmed, if it be found to answer the Purpose to which it is applied.

The lowest Part of the Air being pressed by the Weight of the Atmosphere against the Surface of the Water, and continually rubbing upon it by its Motion, has thereby an Opportunity of attracting and diffolving those Particles with which it is in contact and separating them from the rest of the Water. And fince the Canfe of Solution in this Cafe is the ftronger Attraction of the Particles of Water towards the Air, than towards each other, those that are already dissolved and taken up, will be still further raised by the Attraction of the dry Air which lies over them, and thus will diffuse themselves, rifing gradually higher and higher, and thereby leave the lowest Air not so much faturated.

faturated, but that it will be still able to dissolve and take up fresh Particles of Water. And thus Ice or Snow will evaporate as well as Water, its Particles being attracted and dissolved by the Air, which is strongly pressed against its Surface; for the Heat promotes both Solution and Evaporation, yet we do not find that in either Case any sensible Degree of it is absolutely necessary.

In this Manner will AQUEOUS VAPOURS ASCEND flowly into the Atmosphere, even when we suppose the Air almost at rest, for I believe it is never perfectly so. But the Solution of Water in Air, and the Ascent of Vapours, is greatly promoted by the Motion of the Winds, which bring fresh and drier Air into the Place of that, which may be already faturated and loaded with Moisture, earrying it, together with its Moisture, into the higher Parts of the Atmosphere, and dispersing it into all Quarters.

If we should now suppose the Atmosphere to remain always in the same State as to Heat and Cold, and to have always the fame Denfity; when it was once faturated with Water, all Evaporation would cease, and the Vapours already raised would always remain fuspended; for a Fluid, while it retains the fame Heat and Denfity, will never let go the Particles of a Body that it has dissolved. We must therefore confider what are the Caufes which occasion the Air sometimes to part, with the Water it has diffolved, and which thereby keep up a continual Circulation of Vapours; and these I shall shew to be the frequent Viciffitudes of Heat and Cold. Condensation and Rarefaction, to which the Atmosphere is subject.

As to the Effects of Heat and Cold, I have already shewn that the former promotes, and the latter checks, or in some Measure hinders Evaporation as well as other Solutions; of which I gave an Instance in the Vapours that are suspended during the Heat of the Day, but by the Cold of the Night are precipitated and suffered to coalesce into Drops of Dew.

From the Snow's lying fo long on the Tops of Mountains, we find that the higher Parts of the Atmosphere are much colder than the lower. Now tho' Va-. pours are first raised, and abound most in the lower Parts of the Atmosphere, yet they cannot there be formed into Clouds, because the Heat that helped to dissolve them, helps also to keep them dissolved. But when they are carried by the Winds into the higher Parts, where the same Heat is wanting, the cold Air will not be able to keep in a State of Solution all that are carried up, but must suffer some of them to coalesce into small Particles, which flightly attracting each other and being intermixed with Air will form CLOUDS. having the very fame Appearance with Steam or Smoke, which also confifts of fmall Particles of Water mixed with Air, and not yet diffolved in it. These Clouds, when first formed, will remain suspended, tho' they confift of Water, as well as Air: because the Weight of their Particles will not be able to overcome the Refistance they must meet with in descending through the D 3 Air.

Air. For when Bodies are diminished. their Quantities of Matter to which their Weights are proportional, decrease faster, or in a greater Ratio, than their Surfaces to which the Refistance they meet with is proportional, and therefore in very fmall Particles, this Refistance may become greater than their Weight. The different Heights at which Clouds are formed, depends on the Quantity of Vapours carried up, and the Degrees of Heat in the upper Parts of the Atmosphere; for the Vapours may always afcend till they meet with Air fo cold or fo thin that it is not able to keep in a State of Solution all that are carried up; hence Clouds are generally higher in Summer than in Winter. When Clouds are much increased by a continual Addition of Vapours, and their Particles are driven close together by the Force of the Winds, they will run into Drops heavy enough to fall down in RAIN. Sometimes the Clouds are frozen before their Particles are gathered into Drops, and then fmall Pieces of them, being condensed and made heavier by the Cold, fall down in thin

thin Flakes of Snow, which appear to be Fragments of a frozen Cloud; but if the Particles be formed into Drops, before they are frozen, they become HAIL-STONES.

When the Air is replete with Vapours, and a cold breeze fprings up, as it often does from the Sea, the Solution of these Vapours is checked, and Clouds are formed in the lower Parts of the Atmosphere, and compose what we call a Mist or Fog. This generally happens in a cold Morning, but when the Sun has been up for some Time, the warm Air again dissolves those watery Particles, and it frequently clears up.

In a hot Summer's Day, the Air lying over wet Marshy Ground is copiously filled with aqueous Vapours, 'till the Air growing cooler after Sun-set will not be able to keep all those Vapours dissolved, but must let some Part of them unite quickly into very small visible Particles, and form those Mists which appear to rise from

from Marshy Grounds in a Summer's Evening. The Vapours near the Ground being more dense and copious, will be first affected by the cold, and afterwards those that are thinner and higher up, so that the Mist will be low at first, but will encrease in Height afterwards.

After a warm and unclouded Day in Summer there falls abundance of Dew. and the Air scarce recovers its clearness 'till towards Morning, when it is pretty well cooled: but on the first Return of Heat, at Sun-rise or a little before it, the Water, which is then plentifully spread over the Ground and the Leaves of Trees and Plants in very fmall Drops, begins again to diffolve, and while it is diffolving occasions that HAZINESS so observable in a hot Summer's Morning about Sun-rife; and for some Time after. Here it may be proper to observe, that when the Particles of Water are of a certain Size, they will tender the Air equally opake, whether they are passing into a State of Solution, or returning from it.

Those

Those cold thick Morning Fogs I mentioned just now are often attended with a very light fmall Rain; for the Vapours are then returning fast from a State of Solution, and we fee the Drops, at their first Formation, and they are fuch as we generally meet with in passing over high Mountains, where we are in or near the Clouds. So that it feems the Drops of Rain are very small when first formed in the Clouds; but being driven about by the Motion of the Air in their Descent, fome of them will touch each other and run into a Drop of a larger Size, and the greater Space they fall through, the more will their Size be encreased before they come to the Ground. And for this Reason, the Drops which fall from the higher Clouds in Summer are found to be generally larger than they are in Winter, when the Clouds are low. It has been likewise obferved, that the Drops of Rain are remarkably large that fall in fudden Thunder-Showers; of which the Reason may be, that the Lightning burfting from a Cloud and expanding itself greatly, will suddenly remove onisc

remove the Air from its Place, which Air must therefore return to its Place with great Violence, fo that the watery Particles in the Clouds, strongly agitated and driven against each other, will form themfelves into larger Drops than at other Times. Or perhaps it may be faid, that when a Cloud is filled with Lightning, which is the same as the electric Matter. the watery Particles, like other electrified Bodies, will repel each other, but being fuddenly deprived of this repelling Matter, will by their mutual Attraction come together again with some Velocity, and therefore will run into Drops larger than nfual.

When the Wind blows from the South, it is generally warm and comes replete with aqueous Vapours which it has diffolved, but coming into a colder Climate it cannot there keep the fame Quantity of Vapours in a State of Solution as it did before, and consequently must part with some of them and let them precipitate; and therefore Southerly Winds generally bring

bring us Rain. On the other Hand, when the Wind blows from the North, or any point near it, as it is very cold it cannot have dissolved a great deal of aqueous Vapours where it came from, and therefore coming into a warmer Climate it is ready to dissolve more. And on this Account these Winds, if they continue long, are found to be very dry and parching, and are generally attended with fair Weather.

Thus we see that the Air, according to its different States in respect to Heat and Cold, will dissolve and take up, or let go and precipitate the aqueous Vapours, in consequence of which we sometimes perceive Changes of the Weather, even when there is no Change in the Density of the Air, or consequently in the Height of the Barometer.

But Condensation and Rarefaction will also have the like Effects in promoting the Solution of Water in Air, or in occasioning some Part of what has been dissolved to return again into Water and precipi-

tate. It feems reasonable to suppose, that dense Air in which the Particles lie near each other, will be better able to diffolve and keep suspended a Quantity of Water, than the fame Air when diffused through a greater Space. And that this is really fo, we have an experimental Proof. when a Receiver is partly exhausted, we fee the rarefied Air begin to let go the Water it contained, which gathering into fmall Particles appears like Steam or Smoke falling to the Bottom. In order to prove the fame thing by other experiments, when a Cup of Water, or rather Spirit of Wine (which evaporates fafter) had flood for fome Time in a close Receiver full of Air, I rarefied this Air fuddenly, by letting it rush into another Receiver that was exhausted, and immedi-· ately the Vapour, that was before fufpended, gathered into fmall Particles and fell down in a very visible Shower. I also took from the Air-pump a large exhaufted Receiver 20 Inches long, having at the Bottom a Brass Plate, with a Stop-cock in in the Middle of it, when the Stop-cock was opened, the external Air rushing in violently, and being much rarefied, let go the Water it contained, and threw it against the other end of the Receiver, where it stuck on the Glass, and covered it with a thin Dew, which I found to encrease until the Receiver was almost full of Air.

These Experiments prove, that Air, when rarefied, cannot keep as much Water diffolved as it does in a more condenfed State. And hence we must conclude, that when the Atmosphere is faturated with Water, and changes from a denfer to a rarer State, the higher and colder Parts of it especially will begin to let go some of the Water before diffolved; which will form new Clouds, or add to the Size or Number of the Particles before formed, and thereby render them more apt to fall down in Rain. On the contrary, when the Atmosphere changes from a rarer to a denser State, it will then be able to stop the Precipitation of the Water, and again diffolye

dissolve in the Whole, or in Part, some of those Clouds that were formed before, and confequently will render their Particles less apt to run into Drops and fall down in Rain. And thus we generally find by Experience, that the rarefied and condenfed States of the Atmosphere are respectively attended with Rain or fair Weather. Though this does not happen at all Times, for the Air, tho' rarefied, may not then abound much with aqueous Vapours, having already parted with a good deal of So likewise when the Air is dense and heavy, it may then be so much toaded with aqueous Vapours, that we may have Rain even before we can perceive by the Barometer, that the Atmosphere changes to a rarer State. [D]

Upon

[D] The Vapours raised into the Atmosphere will certainly add somewhat to its Weight, but the Difference of the Quantity of Water contained in the Air at one Time and at another cannot make any considerable Change in its Weight. For the Quantity of Rain has been accurately

Upon this Principle, I think we may account for the Changes of the Weather, which usually attend the rifing and falling of the Mercury in the Barometer, better than by faying, that when the Air grows rarer and lighter, it cannot, by the Laws

accurately measured that falls (communibus annis) in feveral Parts of Europe, and by taking these Quantities at a Medium, I find that in any one Place there will generally fall, one Year with another, as much Rain as would amount altogether to the Height of 28 Inches, which is equivalent in Weight to two Inches of Mercury; if therefore we were to suppose this whole Quantity of Rain to be suspended in the Air at one Time, and then to fall before any more Vapours were taken up, the Mercury in the Barometer would, on that Account, fall two Inches. But we cannot make fuch a Supposition, for the Rain falls in small Quantities and at different Times, and the aqueous Vapours are again taken up into the Air immediately; fo that the Difference in the Quantity of Water sustained in the Air, at one Time more than at another, can add by its Weight but very little to the Height of the Mercury in the Barometer, probably not fo much as the tenth Part of an Inch.

E 2

of Hydrostatics, so well support the Clouds and Vapours, and therefore must permit them to fall down in Drops of Rain. For when the Air grows rarer, although the Clouds will descend into a lower and denfer Part of it, yet they will be there fupported, and I do not fee why their Particles should be more apt to run into Drops there, than when they were higher up, unless they received some Addition from the Water deposited among them by the rarefied Air, in the Manner I have just now mentioned. For fince the Air is rarefied gradually, the Clouds can descend but very flowly, and therefore their Particles will not be fo much pressed together by the Refistance they meet with in their Defcent, as they generally are by the Winds which blow upon them.

When the Atmosphere is saturated with Water, and grows colder and rarer than it was before, we shall then perceive the lower Air begin to part with some of the Water it contains, which will fall insensibly to the Ground, or adhere to the Walls

of Houses, or other Bodies exposed to it, and make them become damp or wet. And if the Moisture fettles on the smooth Surfaces of cold Bodies, fuch as Marble or other Stones, whose Pores cannot imbibe it, it will cover them with a kind of Dew, and then these Bodies are vulgarly faid to SWEAT. At this time the Hygrometer being affected by the Moisture will point to WET, and as we perceive from thence, that the Air is disposed to part with the Water it contains, we may generally expect Rain. But when the Air again grows warm or denfe, it will be able again to dissolve and take up the Water it before deposited, and the Moisture on the Bodies exposed to it will disappear, the Hygrometer will point to DRY, and we may then promise ourselves fair Weather.

I observed before * that if a Bottle be filled with a very cold Liquor and exposed

* Page 18.

to warm Air, a Dew will foon be formed on its Surface, by the Moisture which the cooled Air deposites. Now if we suppose this Body still to retain the same Degree of Cold whilft the Air passes over it, the Dew on its Surface will continually encrease and run down its Sides in small Streams of Water. This feems to be exactly the Cafe of Mountains whose Tops reach into the colder Parts of the Atmosphere, and which therefore are themselves colder than the Air in general. For when the Wind blows the lower Parts of the Atmosphere (which are the warmest and most replete with Vapours) against the Sides of the Mountains, it being there stopped in its Course, must necessarily ascend and pass over their Tops; this Air will therefore be confiderably cooled in its Progress up the Sides and over the Tops of the Mountains, and confequently must let go a great Part of the watery Vapours it contains; which will be precipitated in Dew and Moisture, upon the Surface of the Mountains where it will fink into the earthy Parts.

Parts, or infinuate itself into the Chinks and Crevices of Rocks, and being there collected will afterwards break out in Springs and Fountains, and become the Source of RIVERS, which are known to take their Rife in Mountainous Countries. And on this Account we might have fmall Springs and Rivers near Mountains, tho' there were neither Clouds nor Rain. But the Moisture which the Air usually deposites on the Mountains must be confiderably encreased by the Clouds which are driven against them, and accumulated by the Winds, for their Particles being then preffed together will run into fmall Drops of Rain. Befides, it is well known that Mountains gather and retain the Clouds about them by their Attraction, in Consequence of which we often fee fome Clouds continue at Rest on the Mountains, whilst others at a Distance are carried on gently by the Wind. Hence it is that Countries in the Neighbourhood of high Mountains are the most subject to frequent Rains.

Thus

Thus I have shewn how the Ascent of aqueous Vapours and their constant Circulation, by precipitating again in Moiflure and Drops of Rain, will arise from the dissolving Power of the Air, influenced by the Viciflitudes of Heat and Cold, Condensation and Rarefaction; which Causes, as they take Place in different Degrees, will occasion those various States of the Atmosphere in Respect to Dryness or Moisture, which we experience in the feveral Changes of the Weather. To which the Winds contribute very much by heating or cooling, condensing or rarefying the different Parts of the Atmosphere, and by promoting the Solution of Water in Air, as they mix those Fluids together, or (when the Air is already faturated with aqueous Vapours) by pressing together the Particles in the Clouds, and thereby caufing them to run into Drops.

If we may thus, from the known Properties of Solution, account in a fatisfactory Manner for the Ascent and Circulation of aqueous Vapours, and the several Phænomena nomena of the Atmosphere arising from thence; it must be a great Confirmation of the Arguments brought to prove that Evaporation is only a particular Species of Solution; and therefore that they both proceed from the same Cause, viz. the Attraction that obtains between the minute Particles of different Bodies, which is the Means of carrying on so many other Operations of Nature.

And indeed upon this Principle, Air feems better fitted to be a general Solvent than any Fluid we know of; because its Particles, not attracting each other, are more at Liberty to unite themselves to the minute Particles of fuch Bodies as they do attract. And accordingly we find the Atmosphere contains in it Matter of all Kinds. The odoriferous Particles of Bodies feem to be ftrongly attracted by the Air, as they are fo very readily dispersed thro it; and Camphor, which is a very light volatile Body, may be entirely diffolved in Air without leaving any Remainder. The Air abounds with Vitriolic and other

other Acids, as is plain from the rufting of Iron exposed to it. It abounds also with fulphurous, nitrous, and other inflammable Particles, as appears by the frequent Meteors kindled in it. For we have many Substances, such as strong Acids and effential Oils, which being thrown together will unite with fuch Violence as fuddenly to burst into a Flame, and therefore when the Particles of those Bodies, floating promiscuously in the Air, happen to come together in a fufficient Quantity by their mutual Attraction, (which we know is very ftrong) they must kindle into a Flame, and if many Particles of the inflammable Kind lie contiguous, the Fire will run in a Train and Form, what we call, shooting Stars, and other blazing Meteors. In fhort, the Atmosphere may be confidered as a Chaos containing Particles of all Sorts of Bodies; and as the great Instrument of Nature for keeping up a general Circulation of Matter; and by which not only Water is every where dispersed, but oftentimes the Eggs of Infects and the Seeds

Seeds of Plants are conveyed from Place to to Place, both which have been found in Rain-water, on examining it carefully just after it had fallen; and indeed we sometimes find Insects and Plants in some Places where their Appearance cannot well be accounted for, otherwise than by supposing their Eggs and Seeds to be conveyed thither by the Air.

I shall now mention two other instances in which this diffolving Power of the Air produces Effects of the utmost Impor-Dr. Boerhaave, speaking of that Power or Quality of Air, which makes it necessary for the Preservation of Animal Life, calls it a certain hidden Virtue, not to be accounted for from any of the Properties of Air then discovered. Perhaps we may be led to some Knowledge of it, by confidering on what Account Air may become unfit for Respiration by passing two or three Times thro' the Lungs of an Animal, for we find that an Animal inclosed in fuch Air will foon expire. I think

think we may be fure that one Purpose, at least, for which Air was defigned is, the carrying off that Moisture and other perfpirable Matter which constantly exhales from the Lungs, for this we know it actually does. Now as Air loses nothing of its Elasticity by passing thro' the Lungs, an Animal might still continue to breathe the fame Air, and it would still continue fit for all fuch Purposes in the Animal Oeconomy as may be answered by the alternate Expansion and Contraction of the Lungs in Respiration. But this Air must in a fhort Time become faturated with that Moisture and other perspirable Matter which it meets with in the Lungs, and must then lofe its Power of diffolving and carrying off any more of that Kind of Matter; which Nature intends should be constantly discharged, and which will therefore continually encrease and thereby oppress the Lungs, heat the Blood, or produce fuch other noxious Effects as are more immediately fatal than those arising from the Stoppage of external Perspiration. So. that an Animal inclosed in such Air cannot live long, and will perhaps die somewhat in the same Manner as if it had been drowned. [E] Whether the Air we breathe may deposite, in our Lungs, any Kind

[E] As Air even when incorporated with Water retains its Elasticity, I took it for granted that it would not become less elastic by passing thro' the Lungs of an Animal. But finding that the contrary Opinion was held by some, who supposed that Air, having passed thro' the Lungs of an Animal, became unfit for Respiration by lofing its Elasticity, I resolved to try how the Fact was by the following Experiment. In a Receiver, eight Inches in Diameter and twelve Inches high, having under it a Piece of oiled Leather, I included a pretty large Chicken, and tied the Receiver close down to the Table; thro' a Hole in the Top of the Receiver went a Glass Tube, open at both Ends, cemented round the Hole with Wax; the lower End was immersed in Water, (tinged blue) which stood in a Glass under the Receiver.

In about an Hour after the Chicken was included it grew much distressed, gaped wide and breathed with great Difficulty, and in half an Hour more it seemed almost ready to expire; Kind of Matter necessary to the Support of Life, I cannot pretend to judge, nor is

it

the Infide of the Receiver was then covered with Moisture, which in some Places ran down

in Drops.

Now if the included Air had loft any of its Elasticity by passing thro' the Lungs of this Animal, it could not have pressed so strongly on the Water in the Glass as it did at first, and then the external Air would have pressed thro' the Tube, and appeared coming up through the Water in Bubbles. But no fuch Thing happened, for as foon as the Receiver was tied down, the Water in the Tube rose about one fifth of an Inch above the Water in the Glass, and fo continued during the whole Time of the Experiment, except that it rose and fell near one tenth of an Inch every Time that the Chicken breathed; and these Vibrations of the Water in the Tube I observed grew flower, and moved thro' a greater Space towards the latter End of the Time; which shewed that the Chicken then took in more Air every Time it breathed, than it did at first, endeavouring thereby to throw off the Moisture which then oppressed its, Lungs. After Things had stopped thus above an Hour and a Half, those who faw the Experiment, were convinced that the included

Air

it my Defign to enquire; what has been faid shews the Necessity of fresh Air in Respiration, and by what Property it is adapted to answer one very important Purpofe, and also how Air may soon become unfit for that Purpole. But here I will venture to afk, whether it is not probable, that, in the conflant and quick Evaporation of Moisture from the Lungs, some Degree of Cold may be produced, as in other Evaporations, which, together with the fresh Air taken in, may serve to cool the Lungs and the Blood paffing thro' them? We may see from hence that moist Air must be very unwholesome by its not fufficiently promoting the neceffary Perspiration, both internal and external.

Air is not less necessary for the Support of Fire than of animal Life; for Fire will

Air had not lost any of its Elasticity, though grown quite unfit for Respiration, the Animal being ready to expire in it.

not long continue to burn without a Circulation of Air. Now I suppose this happens, not from its adding any Thing to the Pabulum of Fire, (for Fire feems to be otherwise sufficiently provided with Pabulum) but rather on this Account; that the Air immediately about a Body on Fire is heated and made specifically lighter than the Air at some Distance from it: This hot Air must therefore ascend and carry with it all those minute Particles of different Kinds which are thrown off from the burning Body, and which would otherwife rest upon its Surface, and thereby clog and stop the subtile Vibrations of the burning Matter, in which the Nature of Fire partly consists. If therefore Fire be confined in a close Place, where there can be no Circulation of fresh Air, the Air about it, being foon faturated with the Particles arifing from the burning Matter, will not be able to take up any more of them, and therefore the Fire must go out, fmothered as it were with fuch Particles as are no longer combustible. And hence

it is that Fire burns faster when Air is flrongly blown upon it, for then the Afhes are carried off as fast as they are formed on the Surface of the burning Body, and thereby the Particles that have just taken Fire are kept quite free from any Thing that can impede and clog their vibratory Motion. The Air in this Case will also fpread the Fire quickly thro' the Fuel, by blowing the Particles that are already kindled among those that are not; and perhaps the Motion of the Air in this Cafe may promote the fubtile Vibrations in the burning Matter by which the Fire is propagated thro' its Parts. As the Air contains many fubtile Particles of the inflammable Kind, it is not improbable that these mixing with the groß burning Matter may help to preserve and enliven the Fire; but I think it most probable that Air supports Fire chiefly by carrying off fuch Particles as are burned out, and would therefore obstruct the Progress of the Fire; because we find that the strong elastic Steam of Water driven violently out of the Pipe of

F 3

an * Æolipile, which will carry off those Particles, will also blow up and increase the Fire as well as Air driven from the Bellows, although the Steam does not contain any inflammable Particles.

To this general Observation, that Air is necessary for the Support of Fire, we must admit one Exception; for Nitre will burn in a close Vessel, or in-Vacuo. The Cause of this singular Phænomenon I shall endeavour to assign from what has been said. Nitre, when set on Fire, burns with more Rapidity and Violence than any Body we know of, its burning is a kind of Explosion, and produces a very sierce and elastic Flame, for which Reason it is a necessary Ingredient in Gun-powder, Pulvis fulminans, and all other fulminating Compounds.

^{*} An Æohpile is a hollow Globe of Iron or Copper, into which is screwed a long Pipe, whose End is commonly bent into a Curve: it has a very small Orisice, out of which the Steam issues with great Violence, when Water is boiled in the Æohpile. See it delineated in Fig. 1.

pounds. When therefore a Piece of Nitre takes Fire, its elastic Flame drives off the Fumes and Vapours (with which the Air in the Vessel may be then faturated) and defends the burning Matter, fo that they cannot fettle upon it and extinguish it, as they do other Bodies that burn flowly and without any Explosion. And on this Account Nitre, and other inflammable Matter mixed with it, will burn in close Veffels. or even in Vacuo. This will further appear from confidering the Manner in which Nitre first takes Fire, and the Reafon of its exploding Quality. Nitre will not burn by itself tho' melted and made red hot, but when it comes in Contact with any Body actually on Fire, and which therefore contains an inflammable Matter, or (as it is called) the Phlogiston, it bursts into a Flame. Here the Chymists fay, that the acid Spirit of the Nitre unites fo rapidly with the Phlogiston, which is detached from the burning Matter, that by the Violence of their Congress they both vanish together in a Flame. And they

they prove this to be fo, by throwing strong Acid of Nitre on any thick effential Oil, which confifts almost wholly of the Phlogiston, for then the Mixture will suddenly burst into a Flame with a violent Explosion. Therefore so long as Nitre and the inflammable Matter are thus in Contact, no Fumes or Vapours floating about them can prevent that rapid Union between their Parts which must necessarily make them continue to burn. The Air, which is produced from burning Nitre, may possibly add to the Elasticity of its Flame. But I do not think it probable that this Air can contribute much to keep a large Quantity of Nitre burning fo long as it will do in a close Veffel.

Having thus shewn by what Property
Air produces the Evaporation of Fluids
and several other Effects, I come now to
treat of those Vapours that are raised
merely by Heat. Although the Particles
of Fluids in common Evaporation are
raised

raised into the Atmosphere by the attracting and diffolying Power of the Air, yet in some particular Cases Vapours will be raifed by other Causes. For in some Places the Earth often fends forth hot elastic Vapours that rife into the Air by means of their Elasticity, and carry up with them Mineral and Fossile Particles of different Kinds. Fermentation generates elaftic Vapours which expand themselves into the Air. And the Particles of Water and other Fluids, when sufficiently heated, acquire a repelling Force which separates them from the furface, and throws them upwards into the Air. But all these Vapours foon lose that Elasticity by which they were at first raised, and they must then be retained and kept suspended in the Air by the same Power that keeps up all the Vapours that rife without any Elasticity in common Evaporation.

That the Particles of Steam which rife from hot Water are endued with a repelling Force, appears plainly when Water is boiled boiled in a close Veffel, for then the Steam becomes fo exceedingly elaftic that it will burst the strongest Vessel. In this Case the boiling Water, being ftrongly preffed by the Force of the included Steam, conceives a much greater Heat than it will ever do in an open Veffel; for even when Water is boiled in the open Air it is fomewhat hotter when the Atmosphere is heavy, than when it is light, which shews that Pressure upon boiling Water encreafes its Heat; the Reason of which we may perhaps fee presently. But the most remarkable Phanomenon that attends the boiling of Water, is the large Bubbles which continue to rife from the Bottom fo long as the Water boils, and long after all the Air is driven out of it, concerning which there have been various Opinions. Dr. Boerhaave, in his Elements of Chymistry, proves by feveral Arguments, that thefe Bubbles do not arise from Air, and with Regard to their Production, he feems to be of the fame Opinion with Stairs, (to whose Work he refers) that they arise from from some active Fires residing in the Water. Marriotte, whom he also mentions on this Occasion, calls these Bubbles Fulminations, and supposes that they may proceed from some Kind of faline Particles contained in the Water, which, being heated, act in the fame Manner that the Aurum fulminans does when heated. It has been also a received Opinion that these Bubbles are occasioned by some subtile elaftic Fluid transmitted from the Fire through the Bottom of the Veffel, and this, I think, was the Opinion of Homberg. However I conceive that a Fluid fo subtile as to pass thro' the Bottom of the Veffel. would pass also thro' the Water so easily as not to diffurb it; and therefore I have for some Time suspected, that these Bubbles are formed only by an elastic Steam. in the Manner I shall now describe. The Particles on the Surface of the Water. long before it boils, will, by means of the repelling Force which the Heat introduces among them, rife in Steam, and will infinuate themselves into the Air which yields eafily eafily to them; but those Particles that are pressed against the Bottom, by the Weight of the Atmosphere, and of the incumbent Water, will require a greater Degree of Heat to render them fo elaftic that they shall be able to overcome this Preffure, and expand themselves into a greater Space. Now fince Heat expands Water and makes its Particles repel each other, according to its different Degrees, we must fuppose that these Particles, from their being in Contact with the Bottom of the Vessel, will at length acquire such a Degree of Heat as will give them a repelling Force sufficient to overcome the Pressure they fustain, and to expand them suddenly into those large Bubbles that ascend thro' the Water when it boils violently.

I have lately made some Observations and Experiments which seem to confirm this Opinion. These Bubbles which ascend from the Bottom, Lobserved, always grow less in their Progress upwards, and those

those small Bubbles, that adhere to the Bottom for some Time before they ascend, often disappear entirely before they reach the Surface, which shews that when the Matter they contain, or any Part of it, loses the Heat it had at first, it is again turned into Water.

When Water that has just boiled, or is even confiderably less hot than boiling Water, is poured into a Glass and set under the Receiver of an Air-pump, and the Air is almost drawn out, the Water will boil more violently than it does on the Fire, the Bubbles breaking out from all Parts of it. In this Case, no subtile Fluid can be supposed to rife thro' the Bottom of the Vessel, but the Heat which the Water retains will then give its Particles an elastic Force sufficient to overcome the Pressure of what little Air remains in the Receiver, and will expand them into Bubbles. And that these Bubbles are composed of Steam appears plainly from this Experiment, for as foon as they

they begin to ascend the Receiver is filled with Steam, which being condensed by the Cold runs plentifully down its Sides in Water. From hence we see the Reason why Water in Vacuo boils with a very small Degree of Heat.

After a Vessel of Water had boiled till all the Air-Bubbles were driven out of it, I turned upon its Mouth a large Glass that lay on its Side under the Water; the Bubbles, that afcended under the Glass, remained in the upper Part of it, and forced out the Water it before contained, and then the elastic Matter in the Glass over. turned it, and afcended to the Top in one large Bubble, upon which the Steam on the Surface was much encreased. Now this shews that the Matter contained in these Bubbles, which at first is quite transparent, being a very rare and homogeneous Fluid, appears afterwards like Steam when it is mixed with the Air. But I thought I should make a conclusive Experiment if I could observe the Effects of a

very

very hot Steam conveyed under boiling Water. Therefore when an Æolipile had boiled till all the Air was driven out of the Water it contained, without taking it off the Fire. I immersed its Pipe into a Vesfel of Water which had just been boiled, and immediately the Steam that illued from the Pipe role up in very large Bubbles thro' the Water, and made it appear to boil violently. I then held a large Glass of cold Water, so that the Pipe of the boiling Achipile was immerfed in it; at first none of these Bubbles appeared, for the Steam, being then condensed by the cold Water, was mixed thro' it, making a very loud and uncommon Noise: but as foon as the Water in the Glass grew very hot, this Noise ceased, and the Steam, being no longer condenfed, rofe in large Bubbles, as before, and made the Water appear to boil with great Violence.

These Observations and Experiments feem to discover fully to us the Nature G 2 of

of those Bubbles that ascend thro' boiling Water; and lead me to make some further Remarks on the Degrees of Heat that different Liquors acquire in boiling.

The Parts of a Fluid nearest the Bottom of a Vessel grow hot first, and being then expanded and made lighter, they ascend and change Place with the colder and heavier Parts, which occasions that intestine Motion we perceive in Liquors while they are growing hot. And thus the Heat of the Whole will continue to increase, until those Particles, that are in Contact with the Bottom of the Vessel, acquire such a Degree of Heat as will give them a repelling Force fufficient to overcome the Weight of the Atmosphere, the Weight of the incumbent Fluid, and the Tenacity of its Particles, and then they will be fuddenly expanded into Bubbles of Steam, and afcend quickly to the Top, without communicating this Heat to the furrounding Fluid. For as these Bubbles have a Degree

Degree of Heat but little superior to that of the Fluid, and just sufficient to keep them expanded, if they were to lose any of it, by communicating it to the Fluid in their Ascent, they would all disappear before they got to the Surface, as the very fmall ones do which afcend but flowly; or if the whole Fluid was to grow at once as hot as the Bubbles, it would, like them, be all turned into an elastic Steam. And therefore the Fluid itself cannot grow hotter than it was when these Bubbles began to ascend; but must all boil away in the fame Degree of Heat. [F] Provided it be fuch a Fluid as will not grow denser or more viscid and tenacious by boiling, and of this Kind are Mercury, Water, Spirit of Wine, and feveral others, for these Flu-

^[7] That these Bubbles are really hotter than the other Parts of the Fluid, I found by immersing a Mercurial Thermometer with Fahrenheit's Scale into a Vessel of boiling Water, for it rose one Degree higher when held among the Bubbles, where they were most numerous, than it did in the other Parts of the Water.

ids are found to boil respectively with 600, 212, and 175 Degrees of Heat, and afterwards they do not grow hotter. The Reason of which is plain, for whilst the Pressure upon a Fluid, and its Density and Tenacity continue the fame, the fame Degree of Heat will always be fufficient to feparate its Particles and expand them into Steam; which is the greatest Effect that Fire can produce on any Fluid without actually inflaming it. Hence it is obvious that an additional Pressure on boiling Liquors, or an encrease of their Density or Tenacity, will, by keeping their Particles more strongly together, enable them to bear a greater Degree of Heat before they are expanded into Steam and begin to boil. It is very observable that all oily Liquors, which refract the Rays of Light more strongly than others do, acquire also a much greater Heat in boiling. Thus Oil of Turpentine and other thin effential Oils, that are procured by Distillation, boil with about 560 Degrees of Heat, which however as the boiling continues is always encreasing;

encreasing; the more volatile Parts flying away, and leaving the Residue thicker, more viscid, and susceptible of greater Heat.

Common vegetable and animal Oils begin to boil with 600 Degrees of Heat, which is the fame with that of boiling Mercury, and therefore is the greatest Heat that can be measured by a Mercurial Thermometer. But it has been found, by the Expansion of an Iron Rod, that Oils grow continually hotter by boiling, and at length their Heat encreases so much that they burst into Flame.

There is indeed one Observation, which, if true, would contradict what I have said as to the Heat of boiling Liquors being in some Measure owing to their Viscidity; for it is commonly said that Tar, which is a viscid Liquor, boils with so small a Degree of Heat, that the Workmen skim the Dross off it with their Hands. But this I found to be only the Appearance

Appearance of boiling, for having placed a Veffel of Tar on the Fire; as foon as the Thermometer shewed it to be a little hotter than the human Blood, a great Quantity of Air rose out of it in Froth and Bubbles, carrying up fome Drofs with it, and then I could eafily bear to hold my Finger in it; but foon after, when the Tar began really to boil, the Thermometer rose as high as it does in boiling Water, and was still rising. For Tar, when one Half of it is boiled away, becomes Pitch; and it is well known that boiling Pitch is hotter than boiling Water; fo that this Experiment corresponds exactly with the Theory I have laid down in Regard to the Heat of boiling Liquors.

Hitherto we have considered only the Effects of such Degrees of Heat as are great enough to expand Liquors into large Bubbles and make them boil, or to raise a visible Steam from their Surface, but I find it necessary (for a Reason I shall mention presently) to consider also the Effects

of the leffer Degrees of Heat, down to that which is just sufficient to keep Liquors in a State of Fluidity.

VI CAND VIEST IN CONTROLL WAS ASSESSED ASSESSED

It is generally allowed that Heat keeps Bodies fluid, by caufing their Particles in fome Measure to repel each other, and thereby preventing them from coming into fuch close Contact as would render them hard. Now I shall shew from Experiments that all Degrees of Heat above what is necessary to keep Liquors sluid, will raise from their Surface (provided they are not viscid) some kind of Steam, which, for Diftinction's fake, I shall call an Effluvium. Under a large Glass set a Cup of Water, not hot enough to emit any visible Steam, and let the Glass be exposed to the cold Air, a Dew will soon appear on its Infide. Here an Effluvium is raifed from the Water, but it rifes too flowly and in too fmall a Quantity to become visible till it is condensed on the Glass. As Steam rifes from Hot Liquors more abundantly when the Pressure of the Atmosphere

Atmosphere is taken away, it may be supposed that this Effluvium will also rife more copiously from colder Liquors in the fame Cafe, as we shall fee it really does by what follows. From a great Number of Experiments made with Spirit of Wine, of different Degrees of Strength, I found that, at a Medium, the Quantities loft in the same Time in a close Receiver full of Air, in one only half full of Air, in Air rarefied two and forty Times, and in the open Air, were nearly in the Proportion of 1, 15, 6, and 48. The fame Kind of Spirit was used in each Experiment, the Time was 24 Hours, and the Spirit was contained in equal Cups, fo that their Quantities and their Surfaces were as nearly equal as might be. That all the Spirit used in each Experiment might, be in the fame Circumftances, before I put it into the Cups I drew from it all the Air I could by the Air-pump, which could not rarefy the Air in the Receiver more than two and forty Times, it was necessary to do this, because the Spirit lost five or fix Grains Attrobates

Grains in a few Minutes while the Air was drawing from it by the first Exhaustion of the Receiver, and a Quantity less and less during the fecond and third Exhaustions. A Cup of Water, when in a warm Room, loft one Grain on the first Exhaustion. and when it had afterwards flood in the exhausted Receiver for 24 Hours, it lost two Grains and a Half, while the fame Quantity of Water loft 35 Grains in the open Air; but Ice that was thawing, or Water with Ice in it, did not lose any Thing in the exhausted Receiver, or in a close Receiver full of Air. These Experiments were made in a large Room without a Fire, and the Fluids, whose Losses I compared together, had the same Degree of Heat.

The Spirit of Wine, which is so easily rarefied by Heat, and which has always more Heat than is sufficient to keep it sluid, lost in every Experiment considerably more than Water did in the same Circumstances; and as Water did not lose

any of its Weight, when it had not more Heat than was necessary to keep it fluid, I think the rifing of an Effluvium from these Liquors may justly be ascribed to the repelling Force given to their Particles by certain Degrees of Heat. The Air in the Receiver did not contribute to this Effect, but on the Contrary prevented it, in a great Measure, by its Pressure, for the more Air was drawn from the Receiver, the greater Quantity of this Effluvium arose. I observed, that when the Air was rarefied two and forty Times, the Effluvium that role from the Spirit, which was fometimes near forty Grains in twenty-four Hours, not being supported by a sufficient Quantity of Air. and losing its first Elasticity by being very much expanded, fell by its Weight to the Bottom, and covered it and the lower Parts of the Receiver with Moisture. But none, or very little, of this Moisture appeared when only one Half of the Air was drawn out of the Receiver, for the Effluvium which then ascended (amounting

ing generally to eight or nine Grains) was supported by the remaining Air; but when I rarefied this Air suddenly, as in an Experiment before mentioned, (Page 36.) the Essluvium was immediately gathered into a vast Number of visible Drops, and fell to the Bottom. This plainly shews that the Essluvia which are raised from Liquors, by these very small Degrees of Heat, cannot continue suspended, unless they are supported by a sufficient Quantity of Air.

I thought it necessary to make these Experiments and Observations, in Order to obviate an Objection which might be made to the Principle I have endeavoured to establish. For, as it is found that Fluids lose of their Weight both in an exhausted Receiver, and in the open Air, it might be said that this Loss proceeded from the same Cause in both Cases, and therefore that common Evaporation did not depend on the diffolying

T

e

t-

ng

folving Power of the Air. But from these Experiments, I think, we might give a fufficient Answer to such an Objection. For it appears, first; that Ice, or Water that has no more Heat than is necessary to keep it fluid, lose nothing of their Weight in an exhaufted Receiver, tho' they lofe very confiderably in the open Air. Secondly; The Quantity which the Spirit of Wine loft by Evaporation in the open Air, was eight Times greater than what it loft in the fame Time by an Effluvium, when the Air in the Receiver was rarefied two and forty Times; therefore the Cause of Evaporation must be a much more powerful one than that which raifed the Effluvium. And further, the Quantity loft by Evaporation was forty-eight Times greater than what was loft, in the same Time, by an Effluvium, when the Receiver was full of Air; therefore, supposing the same Effluvium to rife from it in the open Air, we must allow that of the whole Quantity which the Spirit of Wine loft in the eight could be owing to that Effluvium which is occasioned merely by its Heat, consequently forty-seven Parts must have been carried off by some very powerful Action of the Air; which must also be the sole Cause of the Evaporation of Ice or very cold Water, which are found not to emit any Effluvia in an exhausted Receiver. And this Action of the Air I have shewn to be its dissolving Power.

Before we conclude, it may not be amiss to take a general View of the important Purposes which Air is contrived to answer, and of the Means by which it is adapted to these several Purposes. By its Subtilty and Elasticity it is capable of being easily taken into the Lungs of Animals; and by its attracting and dissolving Power it carries on that Perspiration, both internal and external, which we find is necessary to the Preservation of Life. By the same Power it takes

away the supersluous Moisture from Trees and Plants, and thereby promotes Vegetation. By the same Power it raises and sustains aqueous Vapours, and its Heat or Density being diminished, it returns them again in Rain and Dew, and thus keeps up a continual Circulation of Moisture. By the same Power it contributes to the Support of Fire, by carrying off from burning Bodies all such Fumes and Vapours as would otherwise extinguish them.

By its Weight and Pressure on the Surface of Fluids it keeps their Particles together, and enables them to bear (without being dispersed in Steam) such Degrees of Heat as are necessary for all those Uses to which boiling Liquors are applied. By the same Pressure it raises Water in Pumps and other Hydraulic Engines.

And laftly; we may add to these, all the various Purposes to which the Winds

Winds are fubservient; which are too many to be enumerated, and too well known to require being particularly mentioned.

that Cloud States of Hypothetes, when

AVING observed that some have have a late Writers, who endeavour to revive the exploded Hypothesis of an universal Plenum, bring Arguments in Favour of their Opinion from what Sir Isaac Newton says of the Ascent of Comet's Tails in a Direction opposite to the Sun; I was induced to reconsider his Account of that Matter, which, I own, never appeared satisfactory to me; tho' I agree intirely with him that this Phænomenon

82 ON THE NATURE OF THE

Phænomenon affords a fufficient Proof of a Vacuum in the Celestial Regions. As this is a Subject of fome Importance in Physics, I shall, in the following Essay, first, mention fuch Objections as occur to me against Sir Isaac's Opinion as to the Cause of the Ascent of Comet's Tails; and then offer fome Conjectures that may possibly lead to a further Knowledge of this Subject, leaving them to be confirmed or overthrown as future Observations and Experiments shall determine. For I think that Conjectures, or Hypotheses, when rendered probable by fome Experiments, and proposed with Caution, may be of great Use by directing our Enquiries into fome certain Channel.

That I may proceed methodically, I shall begin by relating the Phænomena of Comets as observed by Newton, and other accurate Astronomers, for I shall have Occasion to refer frequently to them.

Phenomenea

It appears that a Comet is a Kind of Planet which revolves round the Sun in a very excentric Orbit, and recedes much farther from the Sun in its Aphelion than any of the Planets; it is not visible until it comes down into the Planetary Regions, and then appears furrounded with a denfe Atmosphere, and from the Side opposite to the Sun, it emits a thinling Train, which we call its Tail. It is at its first Appearance very fhort, and encreases as the Comet approaches towards the Sun, and immediately after its Perihelion, the Tail is longest and most luminous, and then is generally observed to be somewhat bent, and to be convex towards those Parts to which the Comet moves; the Convex Side being rather brighter and better defined than the Concave Side. When the Tail arrives at its greatest Length, which in fome Comets has been computed to be 60 or 70 Millions of Miles, it quickly decreases and foon vanishes entirely, about the fame Time that the Comet itself ceases to be feen. The Matter of which the Tail

84 ON THE NATURE OF THE

Tail is formed is exceedingly rare, and so very pellucid that the Light of the smallest Stars suffers no Diminution in passing thro' it, for Sir Isaac Newton observes:

- ' The extraordinary Rarity of Comet's
- 'Tails may be collected from the Stars
- fhining thro' them; for the smallest
- Stars are observed to shine without any
- Loss of Splendor thro' the Tails which
- ' are of an immense Thickness, and
- ' are also illuminated by the Light of the
- Sun. *

These are the principal Phænomena of Comets, and it is from hence we must deduce whatever we can know of the Substance of which the Tails confist, or of the Reason why they are always thrown off from the Head of the Comet, in a Direction

* Caudarum infignis raritas colligitur ex Aftris per eas Translucentibus.—Per Immensam vero Caudarum Crassitudinem, Luce pariter Solis illustratam, Astra minima absque Clasitatis Detrimento translucere noscuntur. Principia, Page 513. Edit. 2da.

rection nearly opposite to the Sun. And with these Phænomena I propose to compare the Opinions which are commonly received concerning this Matter. Sir . Ifaoc tells us, there were three different Opinions about Comet's Tails, viz. that they were only Rays of the Sun propagated thro' the transparent Head of the Comet. Or that they arose from the Refraction of the Light in its Paffage from the Head of the Comet to the Earth. Or, laftly, that they confifted of Clouds and Vapours continually rifing from the Head of the Comet, and going off in a Direction opposite to the Sun. The first and second of these Opinions he refutes, and adopts the third, and proves by feveral Arguments, that the Tail must consist of some Kind of Vapour arising continually from the Head of the Comet. The Caufe of its ascending always from the Sun, he affigns in another Paragraph, which I shall now quote at Length, translating it as faithfully as I can; it is as follows:

86 ON THE NATURE OF THE

' The Afcent of Tails from the Atmofphere of Comets, and their Progress towards the Parts opposite to the Sun, Kepler ascribes to the Action of the Rays of Light, carrying with them the Mat-. ter of which the Tails confift. And that fo very thin an Air or Vapour ' should yield to the Action of the Rays, in Spaces void of Refistance, is not altogether against Reason; altho in our ' Regions, clogged with refifting Matter, the folar Rays cannot fenfibly impel dense Bodies. Others think that there ' may be some Particles of Matter in their ' own nature light, as well as some that are heavy, and that the Matter of the Tails ' is of the former Sort, and by its Levity afcends from the Sun. But fince the Gravity of all terrestrial Bodies is pro-' portional to their Quantity of Matter, ' and cannot in the same Body be increased or diminished, I suspect that this ' Ascent of the Tails arises rather from the Rarefaction of their Matter. Smoke ' ascends in a Chimney by the Impulse of

of the Air in which it floats; that Air. being rarefied by Heat and its specific Gravity thereby diminished, ascends and carries the Smoke with it. Why then fhould not the Tail of a Comet afcend in the fame Maner from the Sun P for the folar Rays do not agitate any Medium thro which they pals, but in Reflection or Refraction, the reflecting Particles by that Action grow warm, and heat the etherial Air (auram Ethercam) with which they are mixed, which being rarefied by this Heat, and the specific Gravity by which it tended to the Sun being thereby diminished, it will ascend and earry with it the reflecting Particles of which the Tail is formed : it conduces also to the Assem of these Vapours that they revolve round the Sun, and therefore endeavour to recede from it; while the Atmosphere of the Sun either is at Rell, or revolves more flowly with fuch Motion as it can acquire from the Rotation of the Sun round its Axis. These are the Causes of the Ascent of I 2 the

88 ON THE NATURE OF THE

the Tails in the Neighbourhood of the Sun, where the Orbit has a greater Curvature, and the Comet moves in a den-' fer, and therefore heavier Atmosphere of the Sun, and then emits a Tail of a greater Length. For the Tails, which then arise, by preserving their own Motion, and at the fame Time gravitating towards the Sun, will revelve about the Sun in Ellipses just as their Heads do; and by that Motion will always accompany their Heads and adhere to them most freely. For the Gravity of those Vapours towards the Sun will no more cause the Tails to fall from the Heads to the Sun, than it will cause the Heads to fall from the Tails, but they must both, by their common Gravity, fall together to the Sun, or both together be retarded in their Ascent from it: and consequently their Gravity will not ' hinder the Heads and Tails of Comets eafily to receive (from the abovementioned or other Causes) any Postion whatever in respect to each other,

Dill 4

AURORA BORBALIS, &c. 89

or to keep this Polition afterwards most

We find in this Account that Sir Isaac ascribes the Ascent of Comet's Tails to their being rarer and lighter, and moving round the Sun more swiftly, than the solar Atmosphere, with which he supposes them to be furrounded, whill in the Neighbourhood of the Sun; he fays also, that whatever Polition (in Respect to each other) the Head and Tail of a Comet then receive, they will keep the fame afterwards most freely, and in another Place he observes, 'That the celestial Spaces ' must be entirely void of any Power of ' refilting; fince not only the folid Bodies of the Planets and Comets, but even the exceeding thin Vapours, of which Comet's Tails are formed, move thro' those ' Spaces with immense Velocity, and yet with the greatest Freedom. 1 - I cannot help thinking that this Account is li-Atmosphare, they make offerione that?

Principie Page 514 . I Ibid.

mo

90 ON THE NATURE OF THE

able to many Difficulties and Objections, and that it feems not very confiftent with itself, or with the Phænomena.

I do not know that we have any Proof of the Existence of a solar Atmosphere of any confiderable Extent, nor are we any where taught how to guess at the Limits of it. It is evident that the Existence of fuch an Atmosphere cannot be proved merely by the Ascent of Comet's Tails from the Sun, as that Phænontenon may possibly arise from some other Cause. However let us suppose, for the present, that the Ascent of Comet's Tails is owing to an Atmosphere furrounding the Sun, and fee how the Effects arising from thence will agree with the Phænomena. When a Comet comes into the folar Atmolphere, and is then descending almost directly to the Sun, if the Vapours which compose the Tail are raised up from it by the fuperior Denfity and Weight of that Atmosphere, they must rise into those Parts that the Comet has left, and therefore

fore at that Time they may appear in a Direction opposite to the Sun. But as foon as the Comet comes near the Sun, and moves in a Direction nearly at right Angles with the Direction of its Tail, the Vapours which then arife, partaking of the great Velocity of the Comet, and being fpecifically lighter than the Medium in which they move, and being vally expanded thro' it, must necessarily suffer a Refistance immensely greater than what the small and dense Body of the Comet meets with, and confequently cannot poffibly keep up with it, but must be left bebehind, or, as it were, driven backwards by the Refslance of that Medium into a Line directed towards the Parts which the Comet has left, and therefore can no longer appear in a Direction opposite to the Sun. And in like Manner, when a Comet passes its Perihelion, and begins to affcend from the Sun, it certainly ought to appear ever after with its Tail behind it. or in a Direction pointed towards the Sun; for if the Tail of the Comet be fpecifically

cifically lighter than the Medium in which it moves with fo great Velocity, it must be just as impossible it should move foremost, as it is that a Torch moved swiftly thro' the Air should project its Flame and Smoke before it. Since therefore we find that the Tail of a Comet, even when it is ascending from the Sun, moves foremost and appears in a Direction nearly opposite to the Sun. I think we must conclude that the Comet and its Tail do not move in a Medium heavier and denfer than the Matter of which the Tail confilts, and confequently that the constant Ascent of the Tail from the Sun must be owing to some other Caufe. For that the folar Atmofohere should have Density and Weight fufficient to raife up the Vapours of a Comet from the Sun, and yet not be able to give any fenfible Refistance to these Vapours in their rapid Progress thro' it, are two Things inconfiftent with each other. And therefore, fince the Tail of a Comet is found to move as freely as the Body does, we ought rather to conclude that the the celeftial Spaces are void of all refifting Matter, than that they are filled with a folar Atmosphere, be it ever so rare.

Steen coming to us cheened of But there is, I think, a further Confideration which will shew that the received Opinion, as to the Ascent of Comet's Tails, is not agreeable to the Phænomena, and may at the same Time lead us to fome Knowledge of the Matter of which these Tails confift; which I suspect is of a very different Nature from what it has been hitherto fupposed to be. Sir Isac fays, the Vapours, of which the Tail of a Comet confilts, grow hot by reflecting the Rays of the Sun, and thereby warm and rarefy the Meditimo which furrounds them which must therefore afcend from the Sun, and carry with it the reflecting Particles of which the Tail is formed; for he always fpeaks of the Tail as shining by reflected Light. But one would rather imagine, from the Phænomena, that the Matter which forms a Comet's Tail has

167/57

not the least fensible Power of reflecting the Rays of Light. For it appears from Sir Ifaac's Observation, which I have quoted already, that the Light of the. fmallest Stars, coming to us through the immense Thickness of a Comet's Tail, does not fuffer the least Diminution. And yet, if the Tail can reflect the Light of the Sun fo copiously, as it must do if its great Splendor be owing to fuch Reflection, it must undoubtedly have the same Effect on the Light of the Stars; that is, it must reflect back the hight, which comes from the Stars behind it, and by fo doing must intercept them from our Sight, confidering its vast Thickness, and how exceedingly flender a Ray is that comes. from a fmall Stary or if it did not intercept their whole Light, it mult, at least increase their Twinkling. But we do not find that it has even this fmall Effect, for those Stars that appear thro the Tail are not observed to twinkle more than others in their Neighbourhood. Since therefore this Fact is supported by Observations. what

what can be a plainer Proof that the Matter of a Comet's Tail has no Power of reflecting the Rays of Light? and confequently that it must be a felf-shining Substance. But the same Thing will further appear, from confidering that Bodies reflect and refract Light by one and the fame Power: and therefore if Comet's Tails want the Power of refracting the Rays of Light, they must also want the Power of reflecting them. Now, that they want this refracting Power appears from hence, if that great Column of transparent Matter which forms a Comet's Tail, and moves either in a Vacuum, or in forme Medium of a different Denfity from its own, had any Power of refracting a Ray of Light, coming thro it from a Star to us, that Ray must be turned far out of its Way in paffing over the great Distance between the Comet and the Earth; and, therefore, we fhould very fenfibly perceive the smallest Refraction that the Light of the Stars might fuffer in paffing through a Comet's Tail. The Confequence of fuch a Refraction

a Refraction must be very remarkable, the Stars that lie near the Tail would, in some Cases, appear double, for they would appear in their proper Places by their direct Rays, and we should see their Images behind the Tail, by Means of their Rays which it might refract to our Eyes; and those Stars that were really behind the Tail would disappear in some Situations, their Rays being turned afide from us by Refraction. In short, it is easy to imagine what strange Alterations would be made in the apparent Places of the fixed Stars by the Tails of Comets, if they had a Power of refracting their Light, which could not fail to be taken Notice of, if any fuch ever happened. But fince Astronomers have not mentioned any fuch apparent Changes of Place among the Stars, I take it for granted that the Stars feen thro' all Parts of a Comet's Tail appear in their proper Places, and with their usual Colours, and confequently I infer that the Rays of Light fuffer no Refraction in passing thro' a Comet's Tail. And thence I conclude

I conclude (as before) that the Matter of a Comet's Tail has not the Power of refracting or reflecting the Rays of Light, and must therefore be a lucid or selfshining Substance.

version Technical Court diller between in some

And thus if I have argued rightly from the Phænomena, it must appear, that the Tail of a Comet does not consist of aqueous or other Vapours, that shine by restlecting the Light of the Sun, but is a very rare, transparent and lucid Substance, which has no Sort of Effect on the Rays of Light that pass thro' it, and that it is thrown off from the dark Hemisphere of the Comet in a Direction opposite to the Sun, not by the superior Weight and Density of any circumambient Medium, but by some other Cause that has not yet been discovered.

This feems to me to be all the Knowledge we can acquire of the Nature and Properties of that Matter which forms the Tails of Comets, by attending merely to K

I ted 'nword They bas domines of wor

the Phænomenon itself. But perhaps we may be able to extend this Knowledge somewhat further, if we could find any other Phanomenon in Nature which refembles this of Comet's Tails, and can become acquainted with any Kind of Matter that has the fame Properties with that of which they are formed. Now I have of: ten observed a Phænomenon that, I think, very strongly resembles the Tail of a Comet, both in its Appearance, and in the Nature of its Substance. We frequently fee a very rare, transparent, and lucid Substance thrown off, in a Direction nearly opposite to the Sun, from the dark Hemisphere of the Earth, and principally from the more Northern and colder Regions of our Atmosphere. This Appearance is so luminous that it has been from thence called the Aurora Borealis; it is now fo common and well known that I' shall not describe it particularly, and will only take Notice of those Circumstances in which it chiefly refembles a Comet's Tail. Those Northern Lights never appear, at least in any remarkable Degree, foon after Sun-set or before Sun-rife, tho' it may be then dark enough to make them visible, but generally from about ten o'Clock at Night till one in the Morning; and the very long Streams of Light, which issue frequently from the Northern Parts of our Atmosphere, feem still to tend towards the Zenith of that Place where the Spectator is, and fometimes get beyond the Zenith, and appear to the Southward of it; which hiews that thefe Streams of Light tend towards the Vertex of the Earth's Shadow, that is, towards the Part of the Heavens which is opposite to the Sun. From the great Length of these Streams of Light, which feem always moving upwards, we may conclude that they extend to a great Height in the Atmosphere, and probably tile far above it. For by the Accounts we have of an Aurora Borealis, observed in England on the Sixth of March, 1716, it was visible from the West Side of Ireland, to the Confines of Ruffia and Poland, and probably farther

100 ON THE NATURE OF THE

to the East; so that it extended at least over thirty Degrees of Longitude, and from about the fiftieth Degree of Latitude over almost all the North of Europe, and at all Places it exhibited the same Appearances, nearly at the same Time.

Now this great Body of luminous Matter which appears in an Aurora Borealis, being fo very extensive, and sometimes so very bright, must be visible to a Spectator placed at a confiderable Distance from the Earth, and shaded from the Sun's Light; and fuch a Spectator would then fee the Earth attended by a Train of Light in the Form of a Tail. It would probably appear small in Proportion to the Earth's Diameter, it would feem unfleady, changeable in its Shape, and of a short Continuance; but whilft it lasted, it must, both in its Direction, and in the Nature and Appearance of its Light, very much refemble

‡ Phil. Tranf. No. 347.

refemble the Tail of a Comet. And if fuch a Spectator was to observe the Earth for a Year, he might perceive a further Refemblance in this Refpect between the Earth and a Comet: for as the Tail of a Comet appears only a fhort Time before and after its Perihelion, so he would fee this luminous Matter rife from the Earth frequently whilft it was moving from the Autumnal to the Vernal Equinox, thro' the Half of its Orbit that is nearest to the Sun, and very feldom during the other Part of the Year, for we rarely see an Aurora Borealis in the Summer Months. Thus we find that the Matter of an Aurora Borealis and that of a Comet's Tail are very like each other in their Appearance, and in their Situation, with Respect to the Sun and the Bodies from which they flow. And if we examine further, we fhall find that they have exactly the fame Properties; for the Matter of which the Aurora Borealis confifts is not only very rare, transparent and lucid, but is also found to have no Sort of Effect on the

K 3

Rays

Rays of Light which pass thro' it. This' I have often observed, and particularly at one Time when there appeared here an · Aurora Borealis, & which for its Extent, for the Quantity, Brightness and Steadiness of its Lights, was the most remarkable one I ever faw; fome Parts of it appeared like very dense white Clouds, illuminated by a full Moon, but with a more vivid Brightness; and yet thro' one of the densest and whitest of these Clouds, I could plainly fee the fmallest Star in the Pleiades, and could not perceive that its Splendor was at all diminished, or that it even twinkled more than it did before this lucid Matter was interposed, which, as it moved with a quick tremulous Motion, must have at least increased the Twinkling of the Stars, if it had any Sort of Effect on the Rays which paffed thro' it. Since then the Matter of a Comet's Tail, and that of the Aurora Borealis are alike in their Appearance, and agree also in their Properties,

6 October 16 th or 17 th, 1763.

perties, we have some Reason to suppose that they are Substances of the same Kind.

and framous, and when is former its Way Having gained this Step, we may go on in our Enquiries, and try if any other Substance, that we are better acquainted with, has the fame Properties with the Substance of which Comet's Tails and the Aurora Borealis are formed. It is now well known that our Atmosphere abounds with electric Matter, which is more or less contained in all Bodies; this Matter is never visible but whilft it is passing from one Body to another, thro' the Air or a Vacuum, it then appears to be a very rare, fubtile, shining Substance. We often see it flashing from one Cloud to another, or into the Earth, with great Velocity and Brightness, and then we give it the Name of Lightning; and in the fame Manner when we bring our Finger near a Bar of Iron strongly electrified, we see very bright Sparks iffue from it to our Finger. It feems that Air, in its common State of Condensation,

Condensation, resists the Egress of the electric Matter from Bodies in which it is accumulated, especially if they are round and fmooth, and when it forces its Way it feems to come out, as it were, all at once. and in a very condenfed State, and therefore it appears very bright. But if the Air be confiderably rarefied, its Refistance is thereby greatly leffened, and the electric Matter cannot be accumulated in a Body furrounded by fuch Air, for in that Cafe, as fast as it is communicated to the Body it will iffue out from various Parts of it in small Streams of a faint Light, as will appear from fome Experiments I shall have Occasion to mention prefently.

Now fince a folid Body and a Cloud, when electrified in dense Air, will both discharge their Fire in the same Manner, that is, suddenly and in bright Sparks or large bright Flashes, we must conclude, from Analogy, that when they are both electrified in Air much rarefied, they will then

then likewife discharge their Fire in the fame Manner, and confequently that an electrified Cloud, raifed into the higher and rarer Parts of the Atmosphere, will discharge its Fire in continued Streams of faint Light. And as we fometimes fee faint Flashes of Lightning in a Summer Evening after Sun-fet, tho' no Clouds appear; fo if the Vapours which rife into the higher Part of the Atmosphere, tho' not formed into Clouds, carry up with them the electric Matter, they must difcharge it in continued Streams of faint Light, just as a Cloud would do; and those Streams of Light in the higher Parts of the Atmosphere must exactly represent to us the Appearance of an Aurora Borealis. Any one will readily perceive a ftrong Refemblance between the Aurora Borealis and the electric Fire discharged from a Body in rarefied Air, who will make the following Experiments.

Let the Air be almost exhausted out of a Glass Globe or Cylinder, and let it be turned

turned by a Machine and rubbed as ufual; the electric Fire will then appear in the Infide of the Globe, shooting out in various-Branches of faint Light, croffing each other in all Directions, and this Light will fometimes appear tinged with different Colours; when the Air is very much rarefied, the Light appears white, and grows more of a purple Colour as more Air is admitted into the Globe. [A] I found this Experiment fucceed best when I held in my Hand the Cushion with which the Globe was rubbed, and preffed it fometimes closely and fometimes flightly to the Globe. I found that a like Appearance might also be exhibited by the following Experiment. A Cylinder 20 Inches high, and about five in Diameter having a pretty thick Brass Wire put thro' the Top,

⁽A) This Experiment was first made by Mr. Hawksbee, and has fince been often repeated; and I find that the Aurora Borealis has of late been generally supposed to be an electrical Phænomenon, though I have not met with any Attempt to prove that it is so.

was almost exhausted, then being myself electrified, I moved my Finger towards the Top of the Wire, and immediately I faw every Spark that came from my Finger divided into a Multitude of small Streams of Light iffuing from the Wire at right Angles to it, and in different Directions. When I took hold of the Wire I could fee but little Light in the Cylinder, fo found it was necessary to keep my Finger at a finall Distance, and let the electric Matter come to the Wire in fuccessive Sparks. I thought the Lights that iffued from the Wire were brightest when it was oiled, and when the Air was about 30 Times rarer than the outward Air. Several Persons almost as soon as they faw the electric Lights compared them to the Appearance of the Aurora Borealis; and certainly these two Phænomena resemble each other entirely, both in the Colours of their Light, and in the Quickness of their Motions. For when the Air in the Glass-Globe was very much rarefied, the electric Lights appeared very white, and became

became more of a purple Colour as more Air was admitted into the Globe; just fo the long Streams of Light in the Aurora Borealis are very white on their upper Parts, where the Air about them is much rarefied, and are often of a purple Colour on their lower Parts, which are in denfer Air. And as in the Globe the electric Lights appear in greater Abundance when the Air has a particular Degree of Denfity than in other Cases; so the quick Appearing and Disappearing of the Streams of Light in the Aurora Borealis may possibly arise from a Charge of Density in the higher Parts of the Atmosphere. For where the Air is fo very thin it may be fubject to very fudden Condensations and Rarefactions, occasioned by the Motion of the Winds, and I have observed those Lights to appear and disappear more quickly in a windy Night than when it was calm; though their Course or Direction was no ways influenced by the Class-Globe was very much raw berbuiW

elected Laber uppeared very winter and

500000

But the electric Matter appears to be of the fame kind of Substance which forms the Aurora Borealis, and the Tails of Comets, by its having also that remarkable Property of letting the Rays of Light pass thro' it, without having any Sort of Effect upon them. And this I found by feveral Experiments, for I observed that small Rays of Light, passing over sharp Points, and by the Edges of Knives, from whence the electric Matter iffued abundantly, were affected in the very same Manner as when these Points and Edges were not electrified. Having provided a large Pane of Glass properly coated on both Sides with thin sheet Lead, I made two small Holes in the Lead, opposite to each other, for a Ray of Light to pass thro'; and I found this Ray was no more refracted in its Paffage thro' the Holes, when one Side of the Glass was electrified plus, and the other minus, than it was before the Glass was electrified at all, or after the electric Matter was discharged, which shews that the Accumulation, or the Absence of this Matter Matter no way contributed to encrease or diminish the refractive Power of the Glass. I found that when Water was electrified, no Change was made either in its Power of refracting or reslecting the Rays of Light.

I made many other Experiments of the fame Kind, too tedious to describe, and they all led me to conclude that the electric Matter had no Sort of Effect on the Rays of Light that paffed thro' it. Since then the electric Matter feems to be of the fame Nature with that which forms the Aurora Borealis, and abounds much in the Atmosphere, and, when it gets into the rarer Parts of it, will, by its known Properties, exhibit to us an Appearance like that of the Aurora Borealis, we must acknowledge it to be a Caufe really existing, and fufficient to explain this Phænomenon, and therefore we may ascribe the Appearance of an Aurora Borealis to the Rifing of the electric Matter into the upper Regions of the Atmosphere. The following

following Observation will ferve further to confirm this Opinion. In our Summer Months, when the electric Matter is frequently discharged from the lower Clouds in Lightning, and fo returns to the Earth, we scarce ever see an Aurora Borealis: but at other Times, when it is not usually difcharged in Lightning, it may rife higher into the Atmosphere, and will occasion more frequent Appearances of this Kind. And this probably is the Reason why these Appearances are more frequent in cold than in warm Climates, the former being less subject to Storms of Thunder and Lightning than the latter. In Countries that lie far to the North, the Aurora Borealis is faid to thine much brighter than with us, and to appear almost every Night.

As the preceding Confiderations feem to make it probable that the Tails of Comets confift of the fame Kind of Substance which forms the Aurora Borealis, and that this is no other than the electric Matter:

L 2

I shall

I shall assume this as a Principle, and try if I can from thence account, in some Measure, for the Phænomenon of Comet's Tails, and in doing this I shall have an Opportunity of making some Observations which may ferve to flew a further Resemblance between those three Substances that I have compared together. The Earth, and all Bodies near it, contain more or less of the electric Matter, and tho' it may be accumulated in some Bodies, and diminished in others, we cannot be fure that any Body may be totally deprived of it, but on the contrary have great Reason to think it can neither be increafed nor diminished in any Body beyond a certain Degree; we must therefore suppose that it is contained in all Bodies in our folar System. Some Bodies, fuch as Glass, Amber and others, that are called Electrics, attract and retain this Matter more strongly than those do which are called Non-Electrics, for an electric Body will draw this Matter from one that is not electric, against which it is rubbed, and it will

will also stop the electric Matter in its Progress from one Body to another, and therefore an electric Body is called a Nonconductor, in Opposition to other Bodies thro' which the electric Matter readily passes. But we find that any Body, even the most electric, if fufficiently heated, will become a Conductor, or will let the electric Matter pass from it very easily, and therefore we conclude that Heat difposes all Bodies readily to part with the electric Matter they contain, and we have an Inflance in the Tourmalin Stone that fome Bodies will always throw off an electric Matter merely by being heated. Now when a Comet comes down towards the Sun, from Regions of extreme Cold, and begins to acquire some Degree of Heat, it will, like other Bodies, be disposed to part with the electric Matter, which it may possibly contain in great Abundance, and this Matter, when thrown off, will exhibit to us the Appearance of a shining Train, as it does in the Aurora Borealis; and as the Comet comes to its Perihelion, and the

La

Heat

Heat increases, this Matter will issue more abundantly, and the Train or Tail will increase in Length, till upon the Comet's receding from the Sun the Heat will decrease, and this Matter being pretty much exhausted, the Tail will be contracted in its Dimensions, and at length will be too far removed, and grow too faint to be observed.

As a Comet is exposed to vast Extremes of Heat and Cold, Light and Darkness, we may well suppose it to be uninhabited, and if so, it is not necessary that it should turn different Sides to the Sun, but may always keep the fame Face towards it, as the Moon keeps the same Face towards the Earth, and indeed it must do so if its Figure be that of an oblong Spheroid. Now the electric Matter which rifes from the Earth goes off into the colder Regions of the Atmosphere, and in a Direction nearly opposite to the Sun, and I believe we have no Instance of what we call the the Aurora Borealis appearing between the Tropicks.

Tropicks. Why then should not this Matter take the same Course in its Progress from the Head of the Comet, and fly off from its dark Hemisphere, where its Atmosphere is colder and clearer, and where the Vapours are thin, and, rifing more gradually, will give it an Opportunity of rifing along with them; whilst on the other Hemisphere, which is exposed to the Sun, the Vapours must rise very thick, and form Clouds which may intercept the electric Matter in its Progress, and collecting it together may return it back to the Head of the Comet in Lightning, as our Clouds in hot Countries return their electric Matter into the Earth. Befides as we find that the electric Matter passes off from a Body where it is rough or pointed, much more readily than where it is round and fmooth, so it is possible that the Hemisphere of the Comet, which is turned from the Sun, may be so formed as to part with the electric Matter more readily than the other, which is turned towards the Sun, and in whatever Direction the

the electric Matter is thrown off from any Body, we find it continues to move with immense Velocity, as I observed in the Streams of electric Matter which iffued from the Wire in the exhausted Receiver. I observed also that these Streams did not grow much thicker as they advanced in their Course, either in the exhausted Globe or cylindrical Receiver; nor did they feem disposed to expand themselves into the Space that furrounded them, but went straight forward, just as a Ray of solar Light would do. And thus the Matter which iffues from a Comet proceeds in the fame Direction in which it is thrown off, and forms that large Column, which we call the Tail; and we fee that the Matter of which the Tail confifts has very little or no Disposition to expand itself into the furrounding Spaces; for the Tail is not much broader towards the End than near the Head of the Comet. This I think is a most extraordinary Property, both of the electric Matter and of that which forms a Comet's Tail, and which

a further Argument for concluding them to be of the same Nature, for they both fly off from the Body, in which they are, with great Velocity, which seems to argue a repulsive and expansive Force, and yet they proceed as the Rays of Light do without expanding themselves laterally into the Spaces thro' which they pass.

And this remarkable Property feems well worth attending to, in all our Enquiries concerning the electric Matter. At present we are so little acquainted with the true Nature of it, and fo ignorant of the Substance which forms the Body of the Comet, that it is not to be expected, we should be able to say how it can furnish fuch a vast Quantity of this electric Matter, or to affign with Certainty the Reafon why the Tail of a Comet is thrown off from its dark Hemisphere in a Direction opposite to the Sun, rather than in any other Direction. Future Experiments and Observations will either confirm these Conjectures of mine, or fuggest others

more probable; but now we can only argue by Analogy from the rifing of the electric Matter thro' the colder Regions of our Atmosphere in the Aurora Borealis, that the same Effect will take Place in the Atmosphere of a Comet, and from the same Cause, whatever that may be.

Sir Isaac Newton observes that the Tail of the Comet which came to its Perihelion on the eighth of December, 1680, appeared about the Middle of January following to be bent into a Curve. Now as the Tail was convex towards those Parts which the Comet moved, this Bending might feem to arise from its meeting with some refisting Matter; but this Curvature was much less than what would arise from a refifting Matter denfer than the Tail, and whose superior Gravity would be able to raise it up from the Sun; for he tells us that on the 5th of January, when the Tail was 40 Degrees long, its Chord, or a Line drawn from the Head of the Comet to the Extremity of its Tail, made an Angle

Angle of only 8 Degrees with a great Circle paffing thro' the Sun and Comet. But that this Curvature was not owing to any relifting Matter appears from hence, that the Tail must be bent into a Curve. tho' it met with no Refistance; for it could not be a right Line, unless all its Particles were projected in parallel Directions, and with the same Velocity, and unless the Comet moved uniformly in a right Line. But the Comet moves in a Curve, and each Part of the Tail is projected in a Direction opposite to the Sun, and at the same Time partakes of the Motion of the Comet: fo that the different Parts of the Tail must move on in Lines which diverge from each other; and a Line drawn from the Head of a Comet to the Extremity of the Tail will be parallel to a Line drawn from the Sun to the Place where the Comet was, when that Part of the Tail began to ascend, as Sir Isaac observes; and so all the Chords, or Lines drawn from the Head of the Comet to the intermediate Parts of the Tail, will

be respectively parallel to Lines drawn from the Sun to the Places where the Comet was when these Parts of the Tail began to ascend. And therefore, since these Chords of the Tail will be of different Lengths, and parallel to different Lines, they must make different Angles, with a great Circle passing thro' the Sun and Comet, and consequently a Line passing thro' their Extremities will be a Curve.

It is observed that the convex Side of the Tail which is turned from the Sun is better defined, and shines a little brighter than the concave Side. Sir Isaac accounts for this by saying, that the Vapour on the convex Side is fresher (that is, has ascended later) than that on the concave Side, and yet I cannot see how the Particles on the convex Side can be thought to have ascended later than those on the concave Side which may be nearer to the Head of the Comet. I think it rather looks as if the Tail, in its rapid Motion, met with some slight Resistance just sufficient

cient to cause a small Condensation in that Side of it which moves foremost, and which would occasion it to appear a little brighter and better defined than the other Side; which flight Resistance may arise from that fubtile Æther which is supposed to be dispersed thro' the celestial Regions, or from this very electric Matter dispersed in the fame Manner, if it be different from the Æther. Here I must observe that the convex Side of the Tail, which is turned from the Sun, being brighter than the other Side, affords an additional Argument in Favour of what I have afferted, that the Tail does not fhine by reflecting the Sun's Light. And this leads me to fay fomething of that luminous Quality which we observe in the electric Matter, and by which I fuppose the Tails of Comets to shine.

The Writers on Electricity tell us that the electric Matter carries off from Bodies certain fubtile Particles of a fulphurous inflammable Nature, which it kindles as M foon

foon as they are disengaged from the Body, and thence it shines. And this Account is proved from its inflaming other Bodies, fuch as warm Spirits, and from that fulphurous Smell which always attends the electric Matter, and which any one will perceive from his Hand, if he receives the electric Sparks on it for some time, and the same Smell is more strongly perceived in Places that have been struck by Lightning. Now these inflammable Vapours which often abound in the Air, being carried up by the electric Matter, and kindled in the higher Parts of the Atmosphere, will cause it to shine and appear to us in the Aurora Borealis. That the electric Matter can kindle the inflammable Particles that it carries off from Bodies, in Air highly rarified, or even in vacuo, appears from its shining in the upper Part of the Barometer, in which is the most perfect Vacuum we can

But perhaps it may be faid, that without having recourse to the electric Matter, we might suppose the Comet or a great Part of it, to confift of some very combustible Matter which may take fire by a fmall Degree of Heat, and blaze out in fuch Abundance as to occasion the luminous Appearance we call the Tail. And this Hypothesis may appear at first Sight more natural and probable than the one I have fuggefted; yet I imagine it will not be found fo, if we examine it attentively. For if the Comet were to take fire and blaze out as burning Bodies do with us, the elasticity of the Flame might indeed raise it to some Distance from the Body of the Comet, but then it would rife equally on all Sides, or rather to a greater Height on the Side next the Sun, where the Heat is greatest. And a Flame of this kind could not be carried up in a Direction opposite to the Sun, unless it were by the fuperior Denfity and Weight of some furrounding Medium which gravitates to-M 2 wards

wards the Sun; just as we find the Flame of burning Bodies is raifed upwards by the Pressure of the surrounding Air. But I have shewn, in the former Part of this Essay, that a Medium denser and heavier than the Tail must resist and retard its Motion much more than that of the Comet, and therefore could never permit the Tail to move foremost as it fometimes does, but must cause it always to fall behind, and confequently to appear as directed towards the Sun when the Comet has paffed its Perihelion, and is retiring from the Sun. So that in order to account for the constant Ascent of this luminous Matter in a Direction opposite to the Sun, we must have recourse to some Medium that has no fenfible Gravity, and that is apt to move in some particular Direction from the Body in which it is, and with fuch Velocity as to carry the burning Matter to a vast Distance from the Comet before it is entirely confumed. Now I believe we do not know of any Medium that has these Properties except that which we call the electric Matter. For it feems no more affected by the Force of Gravity than the Rays of Light are, and when it moves freely it is apt to go on in the Direction, in which it fet out, as I observed before, and then it moves with fuch a Velocity as we cannot meafure, for it has been found to pass thro' a Wire two Miles and a half in Length, as it were, inftantaneously. This Medium therefore feems not only capable of kindling fuch fubtile inflammable Particles as it meets with in the Comet, but also of carrying them off, before they are confumed, to the vast Distance to which the Tail fometimes extends.

Where the inflammable Particles are quite confumed, the Tail of the Comet must end; and the electric Matter will afterwards be invifibly dispersed thro' the planetary Regions, where it may be gathered up by the Planets in their Courfes round the Sun. For fince we find 1316 /7

M 3

this kind of Matter placed in all Bodies by the Wisdom of Providence, we must conclude it is necessary for carrying on the feveral Operations of Nature; and we know it is very apt to escape from Bodies by its great Subtilty and repelling Force. We fee it rifes from the Earth into the Atmosphere, and is probably going off from thence when it appears in the Aurora Borealis. In like Manner it may fly off from the other Planets, and be continually expanding itself from the Center of our System beyond the Orbit of Saturn. So that it may be necessary it should be brought back again and difperfed among us by the Comets. And it feems to me more probable that Comets were intended for this Use, than for that of fupplying the Planets with Moisture, as as Sir Isaac Newton thought. His Opinion was founded on a Supposition that all Vegetables have their Growth and Increase entirely from Water, and that fince they do not turn again into Water

Water but into Earth, there must be a continual Decay of Moisture, and therefore a fresh Supply of it must be neceffary from time to time.* But this Supposition does not seem to have been fufficiently grounded on Experience. For, fince Sir Isaac wrote, Dr. Woodward, an ingenious Physician, made feveral Experiments on Water and Vegetables growing from it. He shews that all Water contains an earthy Matter, and concludes: 'It is evident, that Water is not the Matter that composes vegetable Bo-' dies; but is the Agent that conveys that 'Matter to them, that introduces and 'distributes it to the feveral Parts for their Nourishment. Where the proper 'terrestrial

* Nam Vegetabilia omnia ex Liquoribus omnino crescunt, dein magna ex parte in Terram aridam per Putrefactionem abeunt, & Limus ex Liquoribus putrefactis perpetuo decidit. Hinc moles Terræ aridæ indies augetur, & Liquores, nisi aliunde augmentum sumerent, perpetuo decrescere deberent, ac tandem deficere.

Principia, Pag. 515. Edit. 2da.

terrestrial Matter is wanting, the Plant is not augmented, tho' never fo much Water ascends into it.'t This is also the Opinion of Dr. Boerhaave, and he affirms from his own Experience, that pure elementary Water cannnot, by repeated Distillations, or otherwise, be converted into Earth. T So that there feems to be no Necessity for supposing a gradual Decay of Moisture in any of the Planets. Belides, if the Comets were intended to fupply the Planets with Moisture, none of them could serve for this Purpose more than once, but must afterwards become useless, tho' they return regularly in their Orbits, which is not agreeable to the Œconomy of Nature. For when the Heat of the Sun had driven all the Moisture it could from a Comet in its Perihelion, where should it afterwards get a fresh Supply? We can scarce suppose the Planets to lofe.

⁺ Philof. Transactions, No. 253.

[#] Elements of Chymistry, Part 2d.

lofe any Moisture by Evaporation, as no Vapours can rife above their Atmofpheres. Or even if any very thin Vapours, Steams or Effluvia of a moist Nature should arise from them, they could not have Heat and Elasticity enough to expand themselves very far. But the electric Matter, from its vast subtilty and velocity, feems capable of making great Excursions from the planetary System, and therefore the several Comets in their long Excursions from the Sun, in all Directions, may overtake this Matter; and attracting it to themfelves may come back replete with it, and being again heated by the Sun, may difperse it among the Planets, and fo keep up a Circulation of this Matter, which we have Reason to think is neceffary in our System.

Sir Isaac, after giving his Opinion that the aqueous Particles thrown off from Comets are taken up by the Pla-

nets

fuspect moreover, That that Spirit which is the least, but the most subtile and the best Part of our Air, and is necessary for supporting the Life of all Things, comes chiefly from the Comets' which shews that he thought the Tails of Comets might consist of something more than watery Clouds and Vapours. What he meant by these Words I cannot say, but I think they are extremely applicable to that kind of Matter which I have supposed comes to us from the Comets; and with which our Air generally abounds.

I shall now recapitulate, in a few Words, the Substance of what has been said. As the Tail of a Comet, tho exceedingly rare, yet meets with no Resistance

† Porro suspicor Spiritum illum qui Aeris nostri pars minima est, sed subtilissima & optima, & ad rerum omnium vitam requiritur ex Cometis præcipue venire.

Principia, Pag. 515.

fistance in its rapid Motion round the Sun, (except so flight a one as can only cause a very small Condensation on that Side of it which moves foremost, and thereby may make it a little brighter than the other Side) it cannot possibly move in a Medium denser and heavier than itself, and therefore cannot be raifed up from the Sun by the superior Gravity of fuch a Medium. And fince the Tail is not capable of reflecting or refracting the Light of the Stars, it cannot shine by reflecting the Sun's Light; and confequently does not confift of Clouds or aqueous Vapours, but is itself a shining Substance, the nature of which it is the buliness of Philosophers to discover. And from what Astronomers fay of the Splendor of Comet's Tails, I am perfuaded they do not shine with such a dull Light, as would be reflected to us by the Clouds or Vapours at fo great a Distance, but with a brifker, tho' a glimmering Light, fuch as would arise from a very thin volatile

volatile burning Matter. And here - I must not omit an Observation of Dr. Halley's, which feems very much to my Purpole. In his Description of the remarkable Aurora Borealis feen in England in the Year 1716, (which I mentioned before) fpeaking of the great Streams of Light, he fays: They fo much refembled the long Tails of Comets, that at first Sight they might well be taken for fuch. And afterwards, This Light feems to have a great Affinity to that which the Effluvia of electric Bodies emit in the Dark. + From whence we find that this accurate Observer perceived a Resemblance between those Substances that I have been comparing together. Now I have shewn that they agree remarkably, not only in their Appearance, but also in such Properties as we can observe in each of them, and therefore I have supposed them to be Substances of the same Nature. I have alfo

⁺ Philof. Transactions, No. 347.

also endeavoured to shew that the electric Matter, from its known Properties, is capable of exhibiting to us all the Phænomena of Comet's Tails, and that we may from thence affign the Use of Comets with more Probability than has hitherto been done.

I have been less scrupulous of propoling fuch Conjectures as occurred to me concerning the Substance that forms the Tail of a Comet, as I confidered that though they should hereafter appear groundless, as very possibly they may, yet others by examining them, and comparing them with future Experiments and Observations, may probably be led to the Discovery of something on this Subject that will be more fatisfactory. And I think every Hypothesis relating to the Effects of the electric Matter, if at all plaufible, may have its Ufe, by inducing us to make further Enquiries into the Nature and Properties of that Kind of Matter, from a Knowledge of which I **fuspect**

134 ON THE NATURE, &c.

fuspect our future Improvements in Natural Philosophy will chiefly arise; especially in that Part of it which relates to Fire and Heat, the Nature of which is at present but little known.

AN

ESSAY

ON THE

PRINCIPLES OF MECHANICES.

iscentatornesistem

AN

E S S A Y

ON THE

PRINCIPLES OF MECHANICKS.*

N this Essay I mean to offer I some Remarks on the Methods that have been commonly used in treating of those Engines that are called the Mechanick Powers; and to give an Account of the Principles on which, I think, we may best explain their Nature and Manner of Acting.

The

* This Essay was read at a Meeting of the Royal Society on the 21st and 23th of April, 1765, communicated in a Letter, dated 13 July N 3 1762,

The many useful Instruments that have been fo ingeniously invented, and fo fuccessfully executed, and the great Perfection to which the Mechanick Arts are now arrived, would naturally incline one to think that the true Principles on which the Efficacy and Operations of the feveral Machines depend, must long fince have been accurately explained. But this is by no Means a necessary Inference; for, however Men may differ in their Opinions about the true Method of accounting for the Effects of the feveral Machines, yet the practical Principles of Mechanicks are fo perfectly known by Experience and Observation, that the Artist is thereby enabled to contrive and adjust the Movements of his Engines with

as

1762, to Matthew Raper, Efq; F. R. S. of Thortey, in Hertfordfhire. Vide Phil. Transactions. Vol. LIH .- [In which fome Improvements have been fince made by the Author.]

as much Certainty and Success as he could do, were he thoroughly acquainted with the Laws of Motion, from which these Principles may be ultimately derived. However, though an Inquiry into the true Method of deducing the practical Principles of Mechanicks from the Laws of Motion, should perhaps not contribute much to promote the Progress of the Mechanick Arts, yet it is an Enquiry in itself useful, and in some Measure necessary; for, since late Authors have used very different Methods of treating this Subject, it may be supposed that no one Method has been looked upon as fatisfactory and unexceptionable. I should therefore wish to contribute towards having this Subject treated with more Accuracy than has been hitherto done.

The most noted Theorem in Mechanicks is this, "When two heavy Bo"dies counterpoise each other by Means
"of any Machine, and are then made

" to move together, the Quantities of " Motion with which one descends and " the other afcends perpendicularly will " be equal." An Aquilibrium always accompanying this Equality of Motions, bears fuch a Refemblance to the Cafe wherein two moving Bodies flop each other when they meet together with equal Quantities of Motion, that many Writers have thought that the Cause of an Aquilibrium, in the feveral Machines might be immediately affigned by faying, that fince one Body always lofes as much Motion as it communicates to another, two heavy Bodies counteracting each other must continue at Rest, when they are fo circumstanced that one cannot descend without causing the other to ascend at the same Time, and with the fame Quantity of Motion; for then should one of them begin to descend, it must instantly lose its whole Motion by communicating it to the other. This Argument, however plaufible it may feem, I think is by no Means

Means fatisfactory; for when we fay that one Body communicates its Motion. to another, we must necessarily suppose the Motion to exist first in the one and then in the other: but in the prefent Case, where the two Bodies are so connected that one cannot possibly begin to move before the other, the descending Body cannot be faid to communicate its Motion to the other, and thereby make it ascend: But whatever we should suppose causes one Body to defcend, must be also the immediate Cause of the other's afcending, fince, from the Connexion of the Bodies it must act upon them both together, as if they were really but one. And therefore, without contradicting the Laws of Motion, I might suppose the superior Weight of the heavier Body, which is in itself more than able to fuffain the lighter, would overcome the lighter, and cause it to ascend with the same Quantity of Motion with which the heavier descends; especially as both their Motions.

tions, taken together, may be less than what the Difference of the Weights, which is here supposed to be the moving Force, would be able to produce in a Body falling freely.

However, as the Theorem abovementioned is a very elegant one, it ought certainly to be taken Notice of in every Treatife of Mechanicks, and may ferve as a very good Index of an Aquilibrium in all Machines; but I do not think that we can from thence, or from any one general Principle, explain the Nature and Effects of all the Mechanick Powers in a fatisfactory Manner, because some of these Machines differ very much from others in their Structures, and the true Reason of the Efficacy of each of them, is best derived from its particular Structure.

The simple Mechanick Powers are usually reckoned six; the Lever, Axle and Wheel, Pulley, Wedge, inclined Plane, and and Screw. I shall consider these Machines separately, and shall explain the Nature and Property of each of them, by shewing from its Structure what Weight it will enable any given Force to sustain.

The Lever is considered as an inflexible Line, void of Weight, and moveable about a fixed Point called its Fulcrum or Prop. The Property of the Lever, expressed in the most general Terms, is this; "When two Weights," or any two Forces, act against each other on the Arms of a Lever, and and are in Equilibrio, they will be to each other inversely as the perpendicular or shortest Distances of their Lines of Direction from the Fulcrum."

This Proposition contains two Cases, for the Directions of the Forces may either meet in a Point or be parallel to each other. Most Writers begin their Demonstration of this Proposition with the

144

the fecond Cafe, which feems to be the fimplest, and from which the other may be deduced by the Refolution of Forces. Archimedes, in his Demonstration, fets out with a Supposition, the Truth of which may reasonably be doubted: For he supposes, that if a Number of equal Weights be suspended from the Arm of a Lever, and at Points equidiftant from each other, whether all these Points be at the fame Side of the Fulcrum, or fome of them on the opposite Side, these Weights will have the same Force to turn the Lever as they would have were they all united and fuspended from a Point which lies in the Middle between all the Points of Sufpension, and may be confidered as the common Center of Gravity of all the separate Weights. Mr. Huygens, in his Mifcellaneous Observations on Mechanicks, says that fome Mathematicians have endeavoured, by altering the Form of this Demonfiration, to render its Defects lefs fenfible, though without Success. He therefore

fore proposed another Proof, which is extremely tedious and prolix, and also depends on a Postulatum that, I think, ought not to be granted on this Occafion; it is this: "When two equal " Bodies are placed on the Arms of a " Lever, that which is furthest from the " Fulcrum will prevail and raise the " other up." Now this is taking it for granted, in other Words, that a small Weight placed further from the Fulcrum will fustain or raise a greater one. The Cause and Reason of which Fact must be derived from the Demonstration that follows, and therefore this Demonstration ought not to be founded on the supposed Self-evidence of what is partly the Thing to be proved.

Sir Isaac Newton's Demonstration of this Proposition is indeed very concise, but it depends on this Supposition. That when from the Fulcrum of a Lever several Arms or Radii issue out in different Directions, all lying in the O

fame vertical Plane, a given Weight will have the fame Power to turn the Lever from which-ever Arm it hangs, provided the Distance of its Line of Direction from the Fulcrum remains the fame. Now it must appear difficult to admit this Supposition, when we confider that the Weight can exert its whole Force to turn the Lever only on that Arm which is the shortest, and is parallel to the Horizon, and on which it acts perpendicularly, and that the Forces which it exerts, or with which it acts perpendicularly, on any one of the oblique Arms, must be inversly as the Length of that Arm, which is evident from the Refolution of Forces.

Mr. Maclaurin, in his View of Newton's Philosophy, after giving us the Methods by which Archimedes and Newton prove the Property of the Lever, proposes one of his own, which, he says, appears to be the most natural one for this Purpose. From equal Bodies, suftaining

taining each other at equal Distances from the Fulcrum, he shews us how to infer that a Body of one Pound (for Instance) will fustain another of two Pounds at Half its Distance from the Fulcrum, and from thence that it will fustain one of three Pounds at a third Part of its Distance from the Fulcrum; and going on thus, he deduces, by a Kind of Induction, what the Proportion is in general between two Bodies that fustain each other on the Arms of a Lever. But this Argument, were it otherwise satisfactory, yet as it cannot be applied, when the Arms of the Lever are incommensurable, it cannot conclude generally, and therefore is imperfect.

There are fome Writers on Mechanicks who, from the Composition of Forces, demonstrate that Case of the general Proposition, relating to the Lever, in which the Directions of the Forces are oblique to each other, and

0 2

meet

meet in a Point: But I do not find that they have had any other Way of proving the fecond Cafe, in which the Directions of the Forces are parallel, but by confidering these Directions as making an Angle with each other, though an infinitely fmall one, or as meeting at an infinite Distance; which Way of reasoning is not to be admitted in Subjects of this Kind, where the Proof should always shew us, directly from the Laws of Motion, why the Conclufion must be true, in such manner that we might fee clearly the Force of every Step from the first Principles down to the Conclusion, which we are prevented from doing when any fuch arbitrary and inconfiftent Supposition is introduced.

From thus confidering the various Proofs that have been given of this fundamental Proposition in Mechanicks, we may fee the Reason why many subsequent Writers have appeared diffatisfied with the former Demonstrations, and have have looked for new ones; I shall now propose two Methods of demonstrating it, merely from the Composition and Resolution of Forces. The Proposition may be expressed as follows.

"When three Forces act upon an inflexible Line, whether straight or crooked, and keep it in Equilibrio, any two of them will be to each other inversly as the perpendicular Distances of their Lines of Direction from that Point to which the third Force is applied."

Let the three Forces E, G, F, (Fig. 2.) act upon three Points A, B; D, in an inflexible Line; and first let the Directions of the Forces E and F (which act on the same Side of the Line) meet in the Point C. Then it is evident that the Force, which is compounded of these two, must act upon the Line A B D in the Direction of a right Line that passeth through the O 3

Point C, consequently the Force G. which fustains this compounded Force. must be equal thereunto, and must act in a contrary Direction; therefore the Force G must act in the Direction of the Line CB. From the Point B draw BH and BK perpendicular to the Directions of the Forces E and F, and draw B M and B N parallel to these Directions forming the Parallelogram B M C N; then, fince these three Forces are in Equilibrio, they must be to each other respectively as the Sides and Diagonal of this Parallelogram to which their Directions are parallel, therefore E is to F as CM, to CN, or M B, that is (because the Sides of a Triangle are as the Sines of the oppofite Angles) as the Sine of the Angle, MBC or its alternate one, BCN to the Sine of the Angle BCM; but, making C B the Radius, B K is the Sine of the former Angle, and B H of the latter, therefore E is to F as BK to BH, fo that the Forces E and F are to each other inverfly as the perpendicular Diftances of their Lines of Direction from the Point B, on which the third Force G acts. Now to compare the Forces F and G together; from the Point A, on which the third Force acts, draw A B and A L perpendicular to the Directions of the Forces G and F, then, as was faid before, F is to G as MB is to CB, but MB is to CB as AB to AL; because, making CA the Radius, A B is the Sine of the Angle M C B, and A L is the Sine of the Angle M C N, or C M B its Supplement to two right ones; therefore the Forces F and G are to each other inverfly as the perpendicular Diftances of their Lines of Direction from the Point A, on which the third Force E acts; and thus the first Case of the Proposition is proved, in which the Forces act against each other in oblique Directions.

We must now consider what Parts of the Forces E and F act against the Force

Force G in Directions parallel to G C. for it is fuch Parts only that really oppose the Force G, and keep it in Æquilibrio, and from thence we shall see what Proportion two Forces must have to each other when they are in Æquilibrio, and act in parallel Directions. Let the three Forces act upon the Points A, B and D, (Fig. 3.) let them be in Aguilibrio, and their Lines of Direction meet in the Point C, as in the preceding Case; then if the Points A, B and D, are not in a right Line, draw the Line A D meeting B C in P, and from P draw P N and P M parallel to the Directions of the Forces E and F; through the Points A and D draw Lines parallel to BC, and thro' B draw a Perpendicular to these Lines meeting them in H and K, from the Point M. draw M O parallel to A D, and meeting B C in O. Now the three Forces E, G and F, that are in Aguilibrio, will be to each other respectively as the Sides of the Triangle C.M P, as

in the preceding Case; but the Force E, which is denoted by the Line M C, may be refolved into two Forces acting in the Directions MO and OC, the former of these only urges the Point A towards D, and the latter acts in direct Opposition to the Force G; in like Manner the Force F. which is denoted by the Line P M, may be resolved into two Forces acting in the Directions O M and PO, the former of which only urges the Point D towards A, and the latter acts in direct Opposition to the Force G; now it is evident that the Force G, which is denoted by the Line PC, is fustained only by those Parts of the Forces E and F, which act against it, in Directions parallel to BC, and are denoted by the Lines OC and PO, which, taken together, are equal to PC, for the other Parts of the Forces E and F which are denoted by MO, are loft, being equal and contrary to each other; if, therefore, instead of the Forces F and E, we suppofe

pose two other Forces R and L, to act on the Points D and A. in Directions parallel to BC, and to keep the Force G in Æquilibrio, it follows, from what has been proved, that R and L, taken together, will be equal to G, and that these three Forces will be to each other respectively as the Lines PO, OC and PC; therefore R will be to L as (PO to OC, that is, as AM to MC, or as AP to PD, or) HB to BK, confequently the Forces R and L are to each other inversly as the perpendicular Diftances of their Lines of Direction from the Point B, to which the third Force is applied. Now to compare the Forces R and G together; fince the Forces R and L may be denoted by BH and BK, and are both together equal to G, that Force will be denoted by the whole Line K H, and therefore R will be to G as B H to KH; fo that these Forces are also to each other inversly as the perpendicular Distances of their Lines of Direction

tion from the Line of Direction of the third Force L; and thus the second Case of the Proposition is proved, in which the Forces act against each other in parallel Directions. If the Point in the inflexible Line, to which one of the Forces is applied, should become a fixed Point, or Fulcrum, round which the Line may turn, it is evident that the other two Forces will continue in Equilibrio, as they were before, and therefore the Property of the Lever, in all Cases, is manifestly proved by this Proposition.

The Center of Gravity of a Body is faid to be that Point which being suftained, or prevented from descending, the Body will continue at rest. From hence it follows, that when a Body hangs freely from a single Point, and continues at rest, its Center of Gravity will lie perpendicularly under the Point of Suspension; for in that Situation only

only it will be fustained, and can defeend no lower.

From this Property, which agrees likewise to the common Center of Gravity of two Bodies, joined together by an inflexible right Line, and which may then be confidered as one, I shall shew that their Center of Gravity is a Point in the Line that joins them together, fo fituated that the Distances of the two Bodies from it are to each other inversly as their Weights. This Theorem concerning the Polition of the common Center of Gravity of two Bodies, which is a very noted one in Mechanicks, I have never feen demonftrated otherwise than by inferring it from the general Property of the Lever: But I think the Method I shall now propose of deducing it directly from the Definition of the Center of Gravity, is the most concise, as well as the most natural, and, befides, it will afford us a very easy Way of demonstrating the Property of the Lever.

Let the Two Bodies A and B (Fig. 4.) be joined by an inflexible right Line passing through their Centers of Gravity, and let them be fuspended from the fixed Point or Pin at P, by the Threads AP and BP, fo that they may hang freely in fuch a Position as their joint Gravity will give them. When these Bodies continue at Rest, their common Center of Gravity must lye directly under the Point of Sufpension, or in the perpendicular Line P L, consequently it must be at the Point C, the intersection of the Lines P L and A B; the Position of which Point, in the Line AB, will be determined by finding out the Proportion between the Segments CA and CB. If the inflexible Line was not interposed between these Bodies, they would move till their Threads coincided with the perpendicular Line PL; fince therefore they are kept afunder by this Line they must urge it with certain Forces in opposite Directions, and these urging Forces P

Forces must be equal, fince the Line on which they act continues at reft; and therefore the Force with which each Body urges the other in the Direction of this Line, may be denoted by the fame Letter U, and we may denote the Weights of the two Bodies respectively by the Letters A and B. Now the Body A is afted upon by three Forces, viz. by its Weight A in the Direction P C, by the Force U, with which the other Body urges it, in the Direction C A, and by the reaction of the Pin in the Direction A P, and fince these three Forces are in Equilibrio, and keep the Body at Reft, they are to each other respectively as the Sides of the Triangle PCA; therefore A is to U, as PC to CA. In like Manner the Body B is urged by three Forces, viz. its Weight B in the Direction PC, the urging Force U in the Direction CB, and the reaction of the Pin in the Direction B P, which Forces are to each other as the Sides of

of the Triangle PCB, therefore U is to B, as CB to PC, and therefore (ex æquo perturbate) A is to B, as CB to CA, consequently the Weights of the Bodies A and B are to each other inversly as their Distances from the Point C, which lies directly under the Point of Suspension, and is therefore their common Center of Gravity.

When two Bodies are connected by an inflexible Line, and this Line is supported by a Prop, so that their Center of Gravity cannot descend, the Bodies must continue at Rest, and will be in aquilibrio. Therefore it is easy to see how, from the Theorem now demonstrated, we may prove the Property of the Lever in that Case where the Directions of the Forces are parallel; and from thence the other Case, in which the Directions are oblique to each other, may be deduced by the Resolution of Forces, as is usually done: And this is the second Method by which

P 2

I faid the general Property of the Lever might be strictly demonstrated.

The Lever is the most simple of all the Mechanick Powers, and to it may be reduced the Balance and the Axis in Peritrochio, or Axle and Wheel. Though I do not consider the Balance as a distinct Mechanick Power, because it is evidently no other than a Lever sitted for the particular Purpose of comparing the Weights of Bodies, and does not serve for raising great Weights or overcoming Resistances as the other Machines do.

When a Weight is to be raised by Means of an Axle and Wheel, it is fastened to a Cord that goes round the Axle, and the Power, which is to raise it, is hung to a Cord that goes round the Wheel. If then the Power be to the Weight as the Radius of the Axle to the Radius of the Wheel, it will just support that Weight; as will easily appear

pear from what was proved of the Lever. For the Axle and Wheel may be confidered as a Lever, whose Fulcrum is a Line passing through the Center of the Wheel and Middle of the Axle. and whose long and short Arms are the Radii of the Wheel and Axle which are parallel to the Horizon, and from whose Extremities the Cords hang perpendicularly. And thus an Axle and Wheel may be looked upon as a Kind of perpetual Lever, on whole Arms the Power and Weight always act perpendicularly, tho' the Lever turns round its Fulcrum. And in like Manner, when Wheels and Axles move each other by Means of Teeth on their Peripheries, fuch a Machine is really, a perpetual compound Lever: and, by confidering it as fuch, we may compute the Proportion of any Power to the Weight it is able to fustain by the Help of fuch an Engine. And fince the Radii of two contiguous Wheels, whose Teeth are applied to each other, are' are as the Number of Teeth in each, or inversly as the Number of Revolutions, which they make in the same Time; we may, in the Computation, instead of the Ratio of these Radii, put the Ratio of the Number of the Teeth on each Wheel; or the inverse Ratio of the Number of Revolutions they make in the same Time.

Some Writers have thought the Nature and Effects of the Pulley might be best explained by considering a fixed Pulley as a Lever of the first, and a moveable Pulley as one of the second, Kind. But the Pulley cannot properly be considered as a Lever of any Kind, for when any Power sustains a Weight by Means of a System of Pullies, that Power will sustain the same Weight if the Pullies be removed, and the Ropes be brought over the Axles on which the Pullies turned. And in this Case I believe no one would say, that these Axles could be considered as Levers.

If the Weight was to be raifed up, there would, in this Case, be a very great Relistance from the Friction of the Ropes on the Axles; and it is merely to avoid this Refistance that Pullies are used, which move round the Axles with but little Friction. I think the best and most natural Method of explaining the Effects of the Pulley (that is, of computing the Proportion of any Power to the Weight it can fustain by Means of any System of Pullies) is by confidering that every moveable Pulley hangs by two Ropes equally stretched, which must bear equal Parts of the Weight; and therefore when one and the same Rope goes round feveral fixed and moveable Pullies, fince all its Parts on each Side of the Pullies are equally firetched, the whole Weight must be divided equally amongst all the Ropes by which the moveable Pullies hang. And confequently if the Power which acts on one Rope be equal to the Weight divided by the Number of Ropes,

Ropes, that Power must fullain the Weight.

Upon this Principle, the Proportion of the Power to the Weight it fultains by Means of any System of Pullies, may be computed in a Manner so easy and natural, as must be obvious to every common Capacity.

The Proportion which any Power bears to the refifting Force it is able to sustain by Means of a Wedge, has has been laid down differently by different Authors, as they happened to consider it in particular Cases. Without examining their several Opinions, I shall endeavour to express this Proposition, which may extend to the several Cases in which the Wedge is applied.

Let the Equictural Triangle ABC (Fig. 5) represent a Wedge, whose Base or Back is AC, and Sides are the Lines,

Lines A B and C B, and whose Height is the Line B P, which bifects, the vertical Angle ABC and also, the Base perpendicularly in P. When a Power is applied to the Wedge, in order to overcome or remove any refifting Forces, it acts perpendicularly on the Back of the Wedge, and the relifting Forces act on its Sides, and they are always supposed to act in Directions that make equal Angles with the Sides. When the refifting Forces and the Power, that acts on the Wedge, are in Equilibrio, the former will be to the latter, as the Height of the Wedge to a Line drawn from the Middle of the Base to one Side, and parallel to the Direction in which the relifting Force acts on that Side.

Let E and F represent two Bodies or two resisting Forces acting on the Sides of the Wedge perpendicularly, and whose Lines of Direction E P and F P meet at the middle Point of the Base,

Base, on which the Power P acts perpendicularly, then will EP and FP be equal, let the Parallelogram ENFP be compleated, its Diagonals PN and E F will bisect each other perpendicularly in H. Now when these Forces (which act perpendicularly on the Sides and Base of the Wedge) are in Equilibrio, they will be to each other as the Sides and Diagonal of this Parallelogram, that is, the Sum of the refifting Forces will be to the Power P, as the Sides E P and F P to the Diagonal P N, or as one Side EP to half the Diagonal PH, that is (from the Similarity of the right-angled Triangles BEP, EHP) as B P, the Height of the Wedge, to E P the Line which is drawn from the Middle of the Base to the the Side A B, and is the Direction in which the refifting Force acts on that Side.

From the Demonstration of this Case, in which the resisting Forces act perpendicularly on the Sides of the Wedge, it appears Power which fustains it, as one Side of the Wedge AB is to the Half of its Breadth AP; because AB is to AP as BP is to EP.

It appears also from hence, that if PN be made to denote the Force with which the Power P acts on the Wedge, the Lines PE and PF which are perpendicular to the Sides, will denote the Force with which the Power P protrudes the resisting Bodies in Directions perpendicular to the Sides of the Wedge.

Let us now suppose, in the second Case, that the resisting Bodies E and F act upon the Wedge in Directions parallel to the Lines DP and OP, that are equally inclined to its Sides, and meet in the Point P. Draw the Lines EG and FK perpendicular to DP and OP; then making PN denote the Force with which the Power P acts on the Wedge,

Wedge, PE and PF will denote the Forces with which it protrudes the refifting Bodies in Directions perpendicular to the Sides of the Wedge, as I observed before: now each of these Forces may be refolved into Two, denoted respectively by the Lines P G and G E, PK and KF, of which GE and KF will be loft, as they act in Directions perpendicular to those of the refifting Bodies, and PG and PK will denote the Forces by which the Power P oppofes the refifting Bodies, by protruding them in Directions contrary to those in which they act on the Wedge; therefore when the refifting Forces are in Aguilibrio with the Power P, the former must be to the latter, as the Sum of the Lines PG and PK is to PN. or as PG is to PH, that is, as PB, the height of the Wedge, is to PD * the

^{* [}PG is to PH as PB to PD.] The right angled Triangles PGE and PED are fimilar

the Line drawn from the Middle of the Base to one Side of the Wedge and parallel to the Direction in which the resisting Force acts on that Side.

From what has been demonstrated, we may deduce the Proportion of the Power to the Refistance it is able to fustain in all the Cases in which the Wedge is applied. First, when in cleaving Timber the Wedge fills the Clest, then the Resistance of the Timber acts perpendicularly on the Sides of the Wedge, therefore in this Case, when the Power which drives the Wedge, is

fimilar, having the Angle at P common to both; therefore PG is to PE as PE to PD; so likewise the rightangled Triangles PHE and PEB are similar, and therefore PH is to PE as PE to PB; therefore the rectangles PG into PD and PH into PB are equal, each of them being equal to the Square of PE, consequently their Sides are reciprocally proportional, that is, PG is to PH as PB to PD.

to the cohesive Force of the Timber, as Half the Base, to one Side of the Wedge, the Power and Resistance will be in Equilibrio.

Secondly, when the Wedge does not exactly fill the Cleft, which generally happens, because the Wood splits to forme Distance before the Wedge. Let ELF represent a Cleft into which the Wedge ABC is partly driven; as the refisting Force of the Timber must act on the Wedge in Directions perpendicular to the Sides of the Cleft, draw the Line P.D in a Direction perpendicular to E L the Side of the Cleft, and meeting the Side of the Wedge in D; then the Power driving the Wedge and the Refistance of the Timber, when they balance, will be to each other as the Line PD to PB the Height of the Wedge.

Thirdly, when a Wedge is employed to separate two Bodies that lie together

on an horizontal Plane, for Inflance two Blocks of Stone; as these Bodies must recede from each other in horizontal Directions, their Refistance must act on the Wedge in Lines parallel to its Base C A: therefore the Power which drives the Wedge will balance the Refistance when they are to each other as PA, Half the Breadth of the Wedge to PB its Height; and then any additional Force fufficient to overcome the Refistance arising from the Friction of the Bodies on the horizontal Plane will feparate them from each other.

The inclined Plane is reckoned by fome Writers among the mechanick Powers; and I think with Reason, as it may be used with Advantage in raifing Weights.

Let' the Line A B (Fig. 6.) reprefent the Length of an inclined Plane, A D its Height, and the Line B D we may call its Base. Let the circular Body

GEF be supposed to rest on the inclined Plane, and to be kept from falling down it by a String CS tied to its Center C. Then the Force with which this Body stretches the String will be to its whole Weight, as the Sine of ABD the Angle of Elevation, to the Sine of the Angle which the String contains with a Line perpendicular to AB the Length of the Plane. For let the Radius CE be drawn perpendicular to the Horizon, and CF perpendicular to AB, and from E draw EO parallel to the String and meeting CF in O. Then, as the Body continues at Rest and is urged by three Forces, to wit, by its Weight in the Direction CE, by the reaction of the Plane in the Direction FC, and by the reaction of the String in the Direction EO; the reaction of the String, or the Force by which it is firetched, is to the Weight of the Body, as EO to CE: That is, as the Sine of (the Angle ECO, which is equal to) ABD the Angle of Elevation.

tion, to the Sine of the Angle EOC, equal to SCO, the Angle which the String contains with the Line CF perpendicular to AB, the Length of the Plane.

When therefore the String is parallel to the Length of the Plane, the Force with which it is firetched, or with which the Body tends down the inclined Plane, is to its whole Weight, as the Sine of the Angle of Elevation, to the Radius, or as the Height of the Plane to the Length. And in the fame Manner it may be shewn, that when the String is parallel to BD, the Base of the Plane, the Force with which it is stretched is to the Weight of the Body, as AD to BD, that is, as the Height of the Plane to its Base. we suppose the String, which supports the Body GEF, to be fastened at S. and that a Force, by acting on the Line A D, the Height of the Plane, in a Direction parallel to the Base BD, drives

 Q_3

drives the inclined Plane under the Body, and by that Means makes it rife in a Direction parallel to AD. Then, from what was proved in the third Case of the Wedge, it will appear, that this Force must be to the Weight of the Body, as AD to BD, or rather in a Proportion somewhat greater: If it makes the Plane move on and the Body rife.

From this last Observation we may clearly shew the Nature and Force of the Screw; a Machine of great Efficacy in raising Weights, or in pressing Bodies closely together. For if the Triangle ABD be turned round a Cylinder whose Periphery is equal to BD, then the Length of the inclined Plane BA will rise round the Cylinder in a spiral Manner; and form what is called the Thread of the Screw, and we may suppose it continued in the same Manner round the Cylinder from one End to the other; and AD the Height

of the inclined Plane will be every where the Distance between two contiguous Threads of this Screw, which is called a Convex Screw. And a Concave Screw may be formed to fit this exactly, if an inclined Plane every Way like the former be turned round the Infide of a hollow Cylinder, whose Periphery is somewhat larger than that of the other. Let us now suppose the Concave Screw to be fixed, and the Convex one to be fitted into it, and a Weight to be laid on the Top of the Convex Screw: Then, if a Power be applied to the Periphery of this Convex Screw to turn it round, at every Revolution the Weight will be raifed up through a Space equal, to the Diftance between the two contiguous Threads, that is, to the Line AD the Height of the inclined Plane BA; therefore fince this Power applied to the Periphery, acts in a Direction parallel to BD, it must be. to the Weight it raises as AD to BD,

175

or as the Diftance between two contiguous Threads, to the Periphery of the Convex Screw: which Distance between two contiguous Threads is to be meafured by a Line parallel to the Length of the Screw. If we now suppose that a Handfpike or Handle is inferted into the Bottom of the Convex Screw, and that the Power which turns the Screw is applied to the Extremity of this Handle, which is generally the Case; then as the Power is removed farther from the Axis of Motion. its Force will be fo much encreased, and therefore so much may the Power itself be diminished. So that the Power, which, acting on the End of a Handle, fuftains a Weight by Means of a Screw. will be to that Weight, as the Distance between two contiguous Threads of the Screw, to the Periphery described by the End of the Handle. In this Case we may consider the Machine as composed of a a Screw and a Lever, or as Sir Ifaac Newton expresses it, Cuneus a vette impulsus.

Of any two or more of these simple Machines combined together, all other Machines, however complicated, are composed. And their Powers and Manner of acting may therefore be explained from the Principles here laid down.

FINIS.
